# Synthetic, Structural, Spectroscopic and Electrochemical Studies of Dinuclear bis $\mu$-Oxo-Bridged Molybdenum(IV) and Tungsten(IV) Half-Sandwich Complexes 

## Dissertation

zur Erlangung des akademischen Grades Doktor der Naturwissenschaften (Dr. rer. nat.)
am Institut für Anorganische und Angewandte Chemie, Universität Hamburg
vorgelegt von

Yan Yu

2013, Hamburg

Diese Arbeit entstand in der Zeit von Oktober 2008 bis Dezember 2013 in der Arbeitsgruppe von Prof. Dr. P. Burger am Institut für Anorganische und Angewandte Chemie, Fakultät für Chemie, Universität Hamburg.

## Gutachter:

Prof. Dr. Peter Burger
PD. habil. Dr. Michael Steiger

## $\mathcal{D E D I C A T I O N}$

To my dear family
In memory of my father...

## Acknowledgements

First and foremost, I would like to thank my PhD thesis supervisor Prof. Dr. Peter Burger for giving me this opportunity to work on this interesting and challenging project. I deeply appreciate the guidance and encouragement he gave me over the years, especially at the beginning of the research when I went through a frustrate time as a international chemical engineering student. I admire his broad knowledge and great scientific attitude towards chemistry which strove me always for the best. The enthusiasm he showed when I achieved nice results really cheered me up. Furthermore, I thank him for for carrying out many DFT calculations. Great thanks also go to PD Dr. Michael Steiger for evaluating my dissertation.

Secondly I want to thank all the former and current members of Burger work group, Dr. Daniel Sieh, Tabea Buban, Mandy Schlimm, Natascha Junker, Marlies Heffter, Friedrich Angersbach-Bludau, Nils Lindenmayer, Bernhard Bugenhagen, Matthias Schreyer, Christian Modrzynski, Sven Schierenbeck, Dr. JanPhilipp Werner and Dr. Andrey Rogachev for the nice working atmosphere they created and the constant willingness to help. Thank you also for all the intense discussions during our Monday group meetings through the years. In particular, great thanks go to Dr. Daniel Sieh for teaching me all the lab techniques from the beginning of my PhD study. In addition, I want to thank the research student Kristina Rossow for the bachelor work dinuclear bis- $\mu$-oxo-bridged molybdenum complexes.

Also, I want to thank all members of the technical service teams in chemistry department at Hamburg University, ie. the NMR spectroscopy, X-ray single crystal, elemental analysis, mass spectroscopy teams etc. Many thanks go to Prof. Dr. Ulrich Behrens for helping me solve complicated crystallographic problems.

Furthermore, I am truly grateful to China Scholarship Council (CSC) for the financial assistance to study abroad. The cooperative graduate program, Key Technologies for Sustainable Energy Systems in Smart Grids, is gratefully acknowledged for the financial support for the last 15 month.

Finally, I would like to give all my thanks to my family and friends. My special thanks go to my dear husband Rongyu Ju for being a rock in my life. Maybe you are not the most romantic guy in the world, but you are the steadiest guy in my life. You may not always be a great boyfriend, but you are a wonderful husband
and I know you will be an amazing father in the future. Thank you for the epic love since high school. Of course, my great thanks go to my parents, parents-inlaw for the endless love and encouragements. And many thanks to family Ju in hamburg, our uncle, aunt and cousins for making hamburg our second hometown. Well, to family Li, Dr. Hongmei Li, Dr. Chao Li, little princess Helen, you are technically our family too, thank you for being such wonderful friends and it is a joy for us being Helen's Gan'ma and Gan'ba. And last, thanks to all our dear friends currently or once lived in hamburg, Dr. Yuna Huang, Yuan Li, Xiaojun Wu, Dr. Wei Shen, Dr. Junyu Lai, Dr. Xiuhua Zhu, Dr. Weiqiang Wang and many others for ski trips, vacations, home cooked meals, coffees, cocktails, swims, badminton plays, fun games and other activities we had together.

## 1. Introduction and Background

The energy consumption of today's society depends to a large degree (about $85 \%)^{1}$ on fossil fuels, which soon meet their limitation of availability. In addition, green-house gases released upon burning of fossil fuels create a significant threat to our current living conditions. This makes the development of alternative renewable energy sources one of the central challenges of $21^{\text {st }}$ century. ${ }^{2-5}$ Solar energy is one of the most promising alternatives as it is available in almost unlimited extent. ${ }^{3}$ The harvest of less than $0.02 \%$ of the incident sunlight on the earth would be enough to fulfill the world's energy requirements. ${ }^{6}$ The most efficient system for the conversion of solar energy into stored chemical energy is natural photosynthesis, which displays a theoretical maximum efficiency of approximately $13 \% .^{7}$ It provides a model for the development of a variety of artificial systems for energy conversion of solar energy. This is known as artificial photosynthesis.

### 1.1. Natural and Artificial Photosynthesis

### 1.1.1. Water Splitting in Photosystem II

Photosynthesis is the process by which autotrophic organisms like plants, algae, and cyanobacteria use light energy to make carbohydrates and oxygen gas from carbon dioxide and water.

$$
6 \mathrm{CO}_{2}+6 \mathrm{H}_{2} \mathrm{O} \xrightarrow{h \nu} \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}+6 \mathrm{O}_{2}
$$

The remarkable light-driven chemistry of water splitting in Photosystem II (PSII) happens in the thylakoid membrane of the chloroplasts. A chlorophyll-a molecule in chloroplast, which is known as P680, absorbs red light of wavelength 680 nm to excite electrons from the reaction center. This electron then pass through a series of molecular intermediates called an electron transport chain into Photosystem I (PSI). (see Figure 1.1) The strong oxidant P680•+ generated by PSII drives water oxidation by means of a catalyst, known as oxygen evolving complex (OEC), to produce $\mathrm{O}_{2}$ and $\mathrm{H}^{+}$. The $\mathrm{H}^{+}$produced by the oxidation of water powered by chemiosmosis is used by ATP (Adenosine Triphosphate) synthase to generate ATP. At the meantime, another chlorophyll molecule called P700 in

Figure 1.1.: Z scheme of photosynthesis. Red light absorbed by photosystem II produces a strong oxidant and a weak reductant. Far-red light absorbed by photosystem I (PSI) produces a weak oxidant and a strong reductant. The strong oxidant generated by PSII oxidizes water, while the strong reductant produced by PSI reduces NADP ${ }^{+}$. [adopted from reference ${ }^{8}$ ]

PS I captures far-red light of wavelengths greater than 680 nm to form a strong reductant, which is able to reduce NADP ${ }^{+}$(Nicotinamide Adenine Dinucleotide Phosphate). PS I regains electrons from the electron transport chain (see Figure 1.1). This is called the $Z$ (for zigzag) scheme of photosynthesis. ${ }^{8}$ In total, through the light reactions in two connected photosystems, light energy was successfully transferred into active chemical energy stored in ATP and NADPH (reduced form of NADP ${ }^{+}$). The ATP and NADPH produced by the light reactions provides the energy and the electrons necessary respectively for the reduction of carbon dioxide to glucose through the Calvin cycle (dark reactions).

The water oxidation catalyst OEC contains a cluster of four manganese ions (in oxidation states of $+2,+3,+4$ and +4 ), a tyrosine $\left(\mathrm{Y}_{z}\right)$ and $\mathrm{Ca}^{2+}, \mathrm{Cl}^{-}$co-factors. ${ }^{9-11}$ The tyrosine reduces $\mathrm{P} 680^{\bullet+}$ to form a tyrosine radical that together with the manganese cluster extracts electrons from water to generate molecular oxygen.

Substantial information about oxygen production in PSII have been provided by flash experiments, electron spin resonance (ESR), and X-ray spectroscopy, but the chemical mechanism of photosynthetic water oxidation on the molecular level has remained obscure. ${ }^{9,11-14}$ Based on a classic hypothesis in photosynthesis research proposed by Kok, ${ }^{15}$ namely the S-cycle model, the $\mathrm{Mn}_{4} \mathrm{Ca}$-cluster undergos five intermediate oxidation states which are labeled as $\mathrm{S}_{0}, \mathrm{~S}_{1}, \mathrm{~S}_{2}, \mathrm{~S}_{3}$, and $\mathrm{S}_{4}$ (the
subscripts indicate the number of electrons extracted from S). The full S-state model presented in Figure 1.2 gives the basic understanding for oxygen evolution at the catalytically active center. Through each photon absorption and charge separation process in P 680 , the oxidizing equivalents accumulate step by step from $\mathrm{S}_{0}$ to $\mathrm{S}_{4}$. Only when the most oxidized $\mathrm{S}_{4}$ state is reached, photooxidation of water occurs and brings the $S_{4}$ state back to the most reduced $S_{0}$ state. $Y_{z}$ functions as an intermediate electron carrier between the $\mathrm{Mn}_{4}$ Ca-cluster and $\mathrm{P} 680^{\bullet+} .{ }^{16}$

Figure 1.2.: Model of the $S$ state cycle of oxygen evolution in PSII(after Tommos and Babcock 1998). [adopted from reference ${ }^{8}$ ]

This $\mathrm{Mn}_{4} \mathrm{Ca}$-cluster contains two active sites, $\mathrm{Mn}(I I)$ and $\mathrm{Mn}(I I I)$ centers in $\mathrm{S}_{0}$ state, which undergo proton coupled electron transfer to its $S_{4}$ state. Different arrangements of the $\mathrm{Mn}_{4} \mathrm{Ca}$-cluster OEC were revealed by EXAFS (Extended X-ray Absorption Fine Structure). The model proposed by Ferreira et al. ${ }^{12}$ for OEC suggest a cubane-like $\mathrm{Mn}_{3} \mathrm{CaO}_{4}$ cluster linked to a forth Mn center by a mono- $\mu$-oxo bridge. The Mn outside the $\mathrm{Mn}_{3} \mathrm{CaO}_{4}$-cubane is the reactive Mn ion, which is in $\mathrm{S}_{4}$ state as a highly electron-deficient intermediate, either a $\mathrm{Mn}(V)$ oxo suggested by Brudvig ${ }^{17}$ or a $\mathrm{Mn}(I V)$ oxyl radical proposed by Siegbahn. ${ }^{18}$ The exact mechanism for oxygen bond formation is not yet fully understood. The model contains a $\mathrm{Mn}(V)$ oxo active site which undergoes nucleophilic attack by a water molecule ligated to $\mathrm{Ca}^{2+}$. Based on DFT (Density Functional Theory) calculations, an alternative mechanism involves the formation of a $\mathrm{Mn}(I V)$ oxyl radical, which is a
oxyl radical attack on the oxo-ligand of the $\mathrm{Mn}_{3} \mathrm{CaO}_{4}$-cubane. Although an article ${ }^{19}$ reported later presented another organisation for the $\mathrm{Mn}_{4} \mathrm{Ca}$-cluster. There is common agreement that the four Mn ions are grouped in a $3+1$ manner. The metal-to metal distances are $2.7 \AA$ for the $\mathrm{Mn}-\mathrm{Mn}$ centers within the grouped three Mn ions and $3.3 \AA$ for the forth Mn ion to the group of three Mn ions, $3.4 \AA$ for the Ca-Mn distance. Radiation damage caused by X-ray diffraction method has been considered as the reason for the inconsistencies between published models. ${ }^{1}$

### 1.1.2. Molecular Approaches towards Solar Water Splitting

The goal of artificial photosynthesis is to replicate the energy fixation process from sunlight to stored chemical energy conducted by green plants. ${ }^{20-24}$ Among various alternatives, hydrogen is particularly attractive because it has very high calorific value, ie. upon combustion it releases $56.7 \mathrm{kcal} / \mathrm{mol}$ energy and leaves no carbon footprint behind. It is essentially very difficult to decompose water since it is thermodynamically unfavorable and involves multiple proton coupled electron transfers. ${ }^{25,26}$ A highly effective photo-catalyst (PC) is urgently sought to lower the activation barrier of the four-electron reaction. The molecular approach offers one of the best solutions to mimic the natural energy conversion.

The water splitting reaction is given in Figure 1.3. This is a highly endothermic process and requires substantial amounts of input energy. The overall reaction of water splitting can be divided into two half-reactions, namely, hydrogen evolving and dioxygen producing. Between the two half-reactions, the oxidation of water to liberate oxygen gas faces the greatest challenge. In an electrochemical cell, the standard potential for the dioxygen producing reaction is $1.23-(0.059 * \mathrm{pH}) \mathrm{V}$ vs the NHE reference electrode, that is 0.82 V under neutral condition (thermodynamic factor). As a rule of thumb, an overpotential of approximately 0.6 V is required to drive the oxidation reaction to take place at observable rate. ${ }^{27}$ As in

$$
\begin{array}{cl}
4 \mathrm{H}^{+}+4 \mathrm{e}^{-} \longrightarrow 2 \mathrm{H}_{2} & \mathrm{E}_{\text {cathodic }}=0 \mathrm{~V}-0.059(\mathrm{pH}) \mathrm{V} \\
\mathrm{O}_{2}+4 \mathrm{H}^{+}+4 \mathrm{e}^{-} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}
\end{array} \mathrm{E}_{\text {anodic }}=1.23 \mathrm{~V}-0.059(\mathrm{pH}) \mathrm{V} .
$$

Figure 1.3.: Nernstian potentials for the two half-reactions of water splitting vs Normal Hydrogen Electrode (NHE).
natural photosynthesis of green plants, the two half-reactions can be addressed separately and combined at a later stage into a single device.

With the inspiration of natural photosynthesis, the model for photochemical water splitting should at least consist of the following two components to successfully achieve a real working molecular system for the targeted reaction: ${ }^{20,23,28}$

1) A photosensitizing chromophore capable of directly absorbing light and performing light-induced charge separation events

The phtosensitizer converts sunlight energy into spatially separated electron/hole pairs and followed by excited-state electron transfer quenching. As a photoreaction center, the model at least consists of an electron donor (or acceptor) chromophore and an additional electron acceptor (or donor), i.e. C-A or D-C. In order to access a spatially charge separated state and hence a longer time scale before charge recombination, the molecular device has to compliant with a Donor-Chromophore-Acceptor (D-C-A) structure to have a better chance to achieve real functional model. The excited chromophore is either oxidatively quenched by the electron acceptor, $\mathrm{D}-\mathrm{C}^{*}-\mathrm{A} \rightarrow \mathrm{D}-\mathrm{C}^{+}-\mathrm{A}^{-}$, or reductively quenched by the electron donor, $\mathrm{D}-\mathrm{C}^{*}-\mathrm{A} \rightarrow \mathrm{D}^{+}-\mathrm{C}^{-}-\mathrm{A}$. In organometallic complexes, the incident light triggers metal to ligand charge transfer (MLCT) transitions. Further electron transfer derived by free-energy gradient, $\mathrm{D}^{-} \mathrm{C}^{+}-\mathrm{A}^{-} \rightarrow \mathrm{D}^{+}-\mathrm{C}^{-} \mathrm{A}^{-}$or $\mathrm{D}^{+}-\mathrm{C}^{-}-\mathrm{A} \rightarrow \mathrm{D}^{+}-\mathrm{C}-\mathrm{A}^{-}$, results in relatively long-lived charge separated oxidative and reductive equivalents.
2) Electron relay catalysts for water oxidation and proton reduction

Electron transfer from $\mathrm{A}^{-}$to a catalyst for reduction ( $\mathrm{Cat}_{r e d}$ ) and from a second catalyst for oxidation ( $\mathrm{Cat}_{o x}$ ) to $\mathrm{D}^{+}$(as depicted in Figure 1.4) must happen before charge recombination. The repetition of the light absorption-electron transfer sequence is needed to provide the required number of redox equivalents for water

Figure 1.4.: Schematic diagram for electron relay in D-C-A unit.
splitting. Finally, the targeted two half reactions deactivate the proton reduction catalyst ( $\mathrm{Cat}_{r e d}{ }^{-}$) and oxygen evolving catalyst $\left(\mathrm{Cat}_{o x}{ }^{+}\right)$to their original state.

The aforementioned two requirements should be used as a guideline for searching new artificial photosensitizers and active redox catalysts towards solar water splitting.

The success of PSII to convert sunlight energy into stored chemical energy prompts research of light harvest molecular devices. This is dominated by several approaches.

The first of them is based on porphyrins and metalloporphyrins as chromophores and their incorporation into molecular assemblies. ${ }^{21,23,29-31}$ For example, molecular pentads (C-P-P-Q-Q) with two covalently liked porphyrin centers (P-P) that are attached to a carotenoid polyene $(\mathrm{C})$ and a rigid diquinone $(\mathrm{Q}-\mathrm{Q})$ were studied by Gust et. al. ${ }^{23}$ (see Figure 1.5). Photo-excitation of such pentads is based on $\pi \rightarrow$ $\pi^{*}$ transitions of P-P followed by electron transfer results in the charge separated state $C^{\bullet+}$-P-P-Q-Q ${ }^{\bullet-}$ with a lifetime approaching 0.5 ms .

Figure 1.5.: Molecular pentads which mimic photosynthetic energy and electron transfer. (simplified from reference ${ }^{23}$ )

The second approach to light-induced charge separation is based on MLCT excited states of polypyridyl ruthenium and platinum complexes. ${ }^{20,28,32-34}$ The absorption of light promotes an electron from a metal-based $\mathrm{d} \pi$ orbital to a lowlying polypyridyl ligand-based $\pi^{*}$ orbital. As illustrated in Figure 1.6, the oxidizing and reducing abilities of $\left[\mathrm{Ru}(\mathrm{bpy})_{3}\right]^{2+}$ are enhanced by $2.1 \mathrm{eV}\left(\Delta G_{E S}{ }^{\circ}\right)$ due to excitation from the ground state (GS) to the excited state (ES). ${ }^{28}$ Excitedstate redox potentials are calculated from ground-state redox potentials by correction with free-energy difference between two states, i.e. $\mathrm{E}^{o}\left(\mathrm{ES}^{+/ 0}\right)=\mathrm{E}^{o}\left(\mathrm{GS}^{+/ 0}\right)$ - $\Delta G_{E S}{ }^{o} / \mathrm{F}$ and $\mathrm{E}^{o}\left(\mathrm{ES}^{0 /-}\right)=\mathrm{E}^{o}\left(\mathrm{GS}^{0 /-}\right)+\Delta G_{E S}{ }^{o} / \mathrm{F}$. The MLCT exited state of
$\left[\mathrm{Ru}(\mathrm{bpy})_{3}\right]^{2+}$ and its derivatives displayed a lifetime in the 1-10 $\mu$ s time scale. ${ }^{35-37}$

Figure 1.6.: Excited- and ground-state redox potentials (vs SCE in $\mathrm{CH}_{3} \mathrm{CN}$ ) for $\left[\mathrm{Ru}(\text { bpy })_{3}\right]^{2+}$ at $25{ }^{\circ} \mathrm{C} .{ }^{28}$

Both approaches utilize the same underlying physical principles and both employ systematic molecular assembly strategies.

There are different types of catalysts for water oxidation explored by scientists worldwide. The first functional designed molecule for catalytic chemical oxidation of water is reported by Meyer and co-workers in 1982. ${ }^{38}$ That is the so-called "blue dimer", $\left[(\text { bpy })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right) \mathrm{Ru}^{\text {III }} \mathrm{ORu}^{\text {III }}\left(\mathrm{H}_{2} \mathrm{O}\right)(\mathrm{bpy})_{2}\right]^{4+}$, which was primarily oxidized by 4 equivalents of $\mathrm{Ce}^{4+}$.

The water oxidation catalysts were recently reviewed. ${ }^{39-41}$ The most extensively studied homogeneous transition metal catalysts are based on ruthenium (T. J. Meyer, ${ }^{28,38,42-44}$ C. P. Berlinguette ${ }^{45,46}$ ). Homogeneous systems based on iridium, ${ }^{47-49}$ platinum ${ }^{34,50}$ and heterogeneous systems based on cobalt phosphates ${ }^{51-53}$ also received much attention.

The OEC of PSII is known to consist of a tetranuclear manganese cluster with two active catalytic sites (vide supra). For a long time, it was considered that two metal sites are required for effective water oxidation, but a few mononuclear catalysts were also found to be active in catalytic water splitting. ${ }^{54}$ The first organometallic mononuclear ruthenium catalyst, $\left[\mathrm{Ru}(\mathrm{bnp})(\mathrm{MePy})_{2}\left(\mathrm{OH}_{2}\right)\right]^{2+}$, which showed catalytic activity in water oxidation was reported in 2005 (bnp $=4$-tert-Butyl-2,6-di([1', $\left.8^{\prime}\right]$-naphthyride- $\left.2^{\prime}-\mathrm{yl}\right)$ pyridine, Py $=$ pyridine). ${ }^{55}$ Since then several polypyridyl ligands were employed and the ruthenium complex, $\left[\mathrm{Ru}(\text { tpy })(\mathrm{bpy})\left(\mathrm{OH}_{2}\right)\right]^{2+}$, has become the most extensively studied mononuclear catalyst. ${ }^{45,56-58}$

The metal complexes that catalyze the oxidation of water generally require sacrificial electron donors. The design of molecular catalysts for photogeneration of hydrogen and oxygen without utilizing sacrificial oxidants and reductants remains a major challenge. Therefore, only few heterogeneous photocatalytic system based on metal oxides ${ }^{59-63}$ have been reported to decompose water in a nonsacrificial manner. A distinct approach of consecutive thermal hydrogen liberation and light-induced oxygen evolution by a $\mathrm{Ru}(I I)$ hydrido-hydroxo pincer complex was presented by Milstein et al. in 2009, ${ }^{64}$ which drew a lot of attentions. ${ }^{27,65-69}$ They revealed that the light-induced oxygen-oxygen bond formation is an intramolecular process and has highlighted as reductive elimination of hydrogen peroxide. This evidenced that the oxygen bond formation does not necessarily involve metal oxo intermediates.

With regard to the photocatalytic hydrogen productions, early examples of multicomponent photosystems incorporating light absorber, electron relays and hydrogen reduction catalysts were developed. ${ }^{70-72}$ More recently, various Ir-, Ptbased phtosensitizers were employed in cooperation with Rh or Co catalyst to effectively reduce protons. ${ }^{73-75}$ The single-component supramolecular photocatalysts, mainly $\mathrm{Ru}-\mathrm{Pt}^{76} \mathrm{Ru} / \mathrm{Ir}^{7} \mathrm{Co}^{77,78}$ and $\mathrm{Ru}-\mathrm{Ru}^{79}$ bimetallics as well as $\mathrm{Ru}-\mathrm{Rh}-$ Ru trimetallics, ${ }^{80}$ were also developed to combine the role of a photosensitizer and a catalyst for hydrogen reduction. However, there is another promising approach to hydrogen production, which is based on mixed-valence dinuclear transition metal complexes. ${ }^{5,81}$ For instance, Nocera and co-workers have shown that $\mathrm{Rh}^{0} \mathrm{Rh}^{I I}$-based complexes with fine-tuned ligand systems are efficient catalysts for hydrogen production from acidic solution. ${ }^{81}$

The dinuclear tungsten systems are also potential photocatalysts, initiating the research efforts in our group.

### 1.2. State of Research in the Work Group

The chemistry of half-sandwich complexes of tungsten in medium oxidation states was previously established in our group by Dr. Christian Cremer. ${ }^{82-84}$ The previous research are summarized below.

The bipyridyl substituted half-sandwich tungsten (IV) complexes of the type $\mathrm{Cp}{ }^{*} \mathrm{~W}\left(\mathrm{R}_{2} \mathrm{bpy}\right) \mathrm{Cl}_{3}\left(\mathrm{R}=\mathrm{Me}, \mathrm{NMe}_{2},{ }^{t} \mathrm{Bu}\right)$ were obtained in good yields through
one electron reduction of the versatile starting material $\mathrm{Cp}^{*} \mathrm{WCl}_{4}$ with TDAE (Tetrakis(dimethylamino)ethylene) in the presence of bipyridyl donors ${ }^{82}$ (see Figure 1.7). The neutral $\mathrm{W}^{I V}$ complexes were shown to have $\mathrm{C}_{s}$ symmetry (facial isomer) by ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectroscopy, with reduced steric repulsion between the $\mathrm{Cp}{ }^{*}$ and one of the bipyridyl rings than in the meridional isomer. Susceptibility measurements showed that these 18 -electron $d^{2}$-configured complexes are weakly paramagnetic with magnetic moments of 0.5 to $0.8 \mu_{B}$ at room temperature.

Figure 1.7.: Sythetic pathway for bipyridyl substituted half-sandwich $\mathrm{W}^{I V}$, cationic $\mathrm{W}^{I V}$ and dinuclear $\mathrm{W}^{I V} \mathrm{~W}^{I V} \mu$-oxo-bridged complexes. ${ }^{82-84}$

Facile ionization of one chlorido ligand in this electron rich complexes enables the isolation of corresponding cationic tungsten (IV) complexes $\left[\mathrm{Cp}{ }^{*} \mathrm{~W}\left(\mathrm{R}_{2} \mathrm{bpy}\right) \mathrm{Cl}_{2}\right]^{+}$ (for $\mathrm{R}=\mathrm{Me}, \mathrm{NMe}_{2}$ ). Due to the very low solubility of the trichlorido complexes $\mathrm{Cp}{ }^{*} \mathrm{~W}\left(\mathrm{R}_{2} \mathrm{bpy}\right) \mathrm{Cl}_{3}$ for the unsubstitutied and more electron withdrawing Cl substituted bipyridines, another synthetic pathway was sought. The related $\mathrm{W}^{I I I}$ complexes of $\mathrm{Cp}^{*} \mathrm{~W}\left(\mathrm{R}_{2} \mathrm{bpy}\right) \mathrm{Cl}_{2}$ (for $\mathrm{R}=\mathrm{H}, \mathrm{Cl}$ ) have been successfully obtained by using Zn powder to reduce the starting material to give $\left[\mathrm{Cp} \mathrm{WCl}_{2}\right]_{2}$ followed by bipyridyl coordination. ${ }^{84}$ Further oxidation of neutral $\mathrm{Cp}{ }^{*} \mathrm{~W}(\mathrm{bpy}) \mathrm{Cl}_{2}$ complex by ferrocenium leads to the corresponding catioic $\mathrm{W}^{I V}$ complex of $\left[\mathrm{Cp}{ }^{*} \mathrm{~W}(\mathrm{bpy}) \mathrm{Cl}_{2}\right]^{+}$. It should be noted that the magnetic behavior of these cationic tungsten (IV) compounds can be also tuned by variation of the nature of the bipyridyl ligands. ${ }^{84}$ $1 / \mathrm{T}$-dependence of ${ }^{1} \mathrm{H}$ NMR resonance of $\left[\mathrm{Cp} * \mathrm{~W}\left(\mathrm{R}_{2} \mathrm{bpy}\right) \mathrm{Cl}_{2}\right]^{+}$complexes showed
linear behavior for $\mathrm{R}=\mathrm{H}$ (pure triplet state) and deviation from Curie-Weiss behavior for $\mathrm{R}=\mathrm{Me}, \mathrm{NMe}_{2}$ (singlet-triplet spin equilibrium). The more electron donating the substituent, the bigger the HOMO-LUMO energy gap, hence the lower preference for the triplet states.

The half-sandwich trichlorido mononuclear complexes of tungsten(IV) can be cleanly converted to the dinuclear bis $\mu$-oxo-bridged tungsten $(I V, I V)$ complexes, $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}\left(\mathrm{R}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right]^{2+}\left(\mathrm{R}=\mathrm{Me}, \mathrm{NMe}_{2},{ }^{t} \mathrm{Bu}, \mathrm{H}, \mathrm{Cl}\right)$, which are both water soluble and stable. These compounds display remarkable spectro- and electrochemical properties. ${ }^{83}$ Moreover, the redox potentials of these oxo-complexes can be tuned over a wide range by using different $\mathrm{R}_{2}$ bipy ligands and display an excellent correlation with the $\sigma$ Hammett-parameter of the R substituents (Figure 1.8). Therefore, in combination with the strong absorptions in the visible and NIR range (up to $\epsilon=10^{4} \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ ), these systems were deemed to have a high potential as photochemical redox catalysts and might combine the role of a redox catalyst and a photosensitizer.

Figure 1.8.: Dependence of electrochemical properties of complexes on the substituents R in bipyridine ligands and absorbance spectrum of complex $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}\left(\mathrm{R}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right]^{2+}$ representative. ${ }^{83}$

In order to access the electrochemically generated redox couples of $\mathrm{W}^{I V} \mathrm{~W}^{I V}$ oxocomplexes, the chemical oxidation and reduction reactions were carried out. The tricationic paramagnetic tungsten $(I V, V)$ complex $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}\left(\mathrm{Me}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right]^{3+}$ was isolated by one-electron oxidation with ferrocenium. (see Figure 1.9) In contrast to previously investigated Ru complexes, protonation of the novel tungsten $(I V, I V)$ complexes is possible, which is an important step in the hydrogen reduction process. Two equivalents of sodium naphthalenide were used to achieve the diamagnetic tungsten(III,III) complexes of $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}\left(\mathrm{R}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right](\mathrm{R}=\mathrm{Me}$,
$\left.{ }^{t} \mathrm{Bu}\right)$. The X-ray crystal structure of this tungsten(III,III) complex $(\mathrm{R}=\mathrm{Me})$ differs from all other structures and displays a trans arrangement of the $\mathrm{Cp}^{*}$ ligands with a flat $\mathrm{W}_{2} \mathrm{O}_{2}$ ring. Although, the cis geometry is maintained on the time scale of cyclic voltammetry ( CV ) measurement, which is the reason why the process of redox couple $\mathrm{W}^{I V} \mathrm{~W}^{I I I} / \mathrm{W}^{I I I} \mathrm{~W}^{I I I}$ still is electrochemically reversible. The mixed valence mono cationic complex $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}\left(\mathrm{Me}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right]^{+}$was isolated as a side product which showed structural resemblance of cis tungsten $(I V, I V)$ compounds. The lower valent $\mathrm{W}^{I I I} \mathrm{~W}^{I I I}$ complex of $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}\left({ }^{t} \mathrm{Bu}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right]$ is capable of reducing protons to dihydrogen under acidic condition.

$\mathbf{R}=\mathbf{M e}$

$\mathbf{R}=\mathbf{M e}, \mathrm{NMe}_{2},{ }^{\mathrm{t}} \mathrm{Bu}$

$\mathbf{R}={ }^{\mathrm{t}} \mathrm{Bu}$

$\mathbf{R}=\mathbf{M e},{ }^{\mathrm{t}} \mathrm{Bu}$

Figure 1.9.: Reactivity of dinuclear $\mathrm{W}^{I V} \mathrm{~W}^{I V} \mu$-oxo-bridged complexes. ${ }^{83}$

Despite all advantages of the novel dinuclear bis $\mu$-oxo-bridged tungsten(IV,IV) half-sandwich complexes, $\mathrm{H}_{2}$ has not yet been released from neutral to acidic solutions in preliminary irradiation experiments. This might be caused by the short lived excited state, which decays to the ground state before the electron is transferred to the proton.

### 1.3. The Aim and Structure of This Thesis

This dissertational work is aimed to design and synthesize dinuclear group 6 transition metal complexes with improved electrochemical and photophysical properties towards water splitting. In pursuing this goal, the diimine ligands as well as the metal center are to be modified.

Previous work on $\mathrm{W}^{I V} \mathrm{~W}^{I V}$ systems established a strong dependence of the redox potentials on the electron-withdrawing/donating properties of the substituents R of the bipy ligands. The potential for oxidation can be increased by 0.62 V going from $\mathrm{NMe}_{2}$ to Cl substituents of the 4.4 -disubstituted bipy ligand. Even more electron-withdrawing substituents like $\mathrm{R}=$ COOMe are to be used in bipy ligand supposedly leading to even more positive redox potentials. Two new electron-withdrawing 1,10-phenanthroline based ligands, dpphen (4,7-diphenyl-1,10-phenanthroline) and dpq (dipyrido[3,2-f: $\left.2^{\prime}, 3^{\prime}-h\right]$ quinoxoline), will be applied (Figure 1.10). These ligands are well-recognized as photosensitive ligands due to low lying LUMOs with strong $\pi^{*}$ characters. ${ }^{85,86}$ In combination with their electron-acceptor properties, a significant increase of efficiency for light absorbance as well as charge separation is anticipated. Consequently, extended excited state life times of the aforementioned tungsten(IV) and molybdenum $(I V)$ complexes are deemed accessible.

(COOMe) ${ }_{2}$ bpy

dpphen

dpq

Figure 1.10.: New electron-withdrawing ligands used in this thesis.

The redox potentials of molybdenum complexes are supposed to increase with regard to the tungsten complexes, ${ }^{87}$ which offer a better chance to oxidize water. Therefore, the molybdenum(IV) analogues of the dinuclear tungsten(IV) complexes were also to be explored.

In these tungsten $(I V)$ and molybdenum( $I V$ ) organometallic architecture, the Cp * ligands will be employed as donor components and the diimine ligands will perform as acceptors.

The synthesis of various mononuclear half-sandwich tungsten(IV) and molybdenum $(I V)$ complexes will be described in Chapter 2. The synthetic routes, spectroscopic and electrochemical studies of dinuclear $\mu$-oxo-bridged tungsten and molybdenum complexes will be presented in chapter 3 and 4 respectively. In chapter 5, a summary of the thesis will be given. The experimental details will be specified in Chapter 6.

## 2. Mononuclear Half-Sandwich Tungsten(IV) and Molybdenum(IV) Halido Complexes

The organometallic chemistry of the cyclopentadiene ligand is generally well developed. The monocyclopentadienyl halido complexes of d- and f-block transition metals have been reviewed by Poli in 1991.88 The monocyclopentadienyl halido compounds of tungsten and molybdenum in oxidation state $I I,{ }^{89-91} I I I,{ }^{91,92}$ $I V,{ }^{93-98} V,{ }^{99-104} V I^{105,106}$ were extensively studied by Poli, Schrock and Green. In the original work of Cremer, ${ }^{82}$ a new series of $\mathrm{Cp}^{*}\left(\eta^{5}-C_{5} M e_{5}\right)$ tungsten $(I V)$ complexes with an additional bipyridyl ligand, $\left[\mathrm{Cp}{ }^{*} \mathrm{~W}\left(\mathrm{R}_{2} \mathrm{bpy}\right) \mathrm{Cl}_{3}\right]\left(\mathrm{R}=\mathrm{Me}, \mathrm{NMe}_{2}\right.$, $\left.{ }^{t} \mathrm{Bu}\right)$, was prepared by one-electron reduction of the versatile starting material $\left[\mathrm{Cp}^{*} \mathrm{WCl}_{4}\right]$. The synthesis and characterization of dpq, dpphen, (COOMe) ${ }_{2}$ bpy and $\left({ }^{t} \mathrm{Bu}\right)_{2}$ bpy substituted half-sandwich $\mathrm{W}^{I V}$ and $\mathrm{Mo}^{I V}$ halido complexes are presented herein.

### 2.1. Starting Materials

### 2.1.1. Pentamethylcyclopentadienyl Tungsten $(V)$ and Molybdenum( $V$ ) Chlorido Complexes

The starting materials $\left[\mathrm{Cp}^{*} \mathrm{MCl}_{4}\right](\mathrm{M}=\mathrm{W}, \mathrm{Mo})$ were prepared in three reaction steps from the commercially available metal hexacarbonyls (see Reaction Scheme 2.1). Tungsten/molybdenum hexacarbonyl was refluxed with with butyronitrile to give fac- $\mathrm{M}(\mathrm{CO})_{3}(\mathrm{NCPr})_{3},{ }^{107}$ followed by reaction with $\mathrm{Cp}{ }^{*} \mathrm{H}$ to generate $\mathrm{Cp}{ }^{*} \mathrm{M}(\mathrm{CO})_{3} \mathrm{H},{ }^{108}$ which was oxidized with $\mathrm{PCl}_{5}$ to $\mathrm{Cp}^{*} \mathrm{MCl}_{4}(\mathrm{M}=\mathrm{W}, \mathrm{Mo}) .{ }^{99,109}$

Reaction Scheme 2.1: Synthetic pathway of pentamethylcyclopentadienyl tungsten and molybdenum tetra-chlorido starting materials.

The $C_{3 v}$ symmetry of facial $\mathrm{W}(\mathrm{CO})_{3}(\mathrm{NCPr})_{3}$ compound was verified by infrared spectroscopy, which showed two $v(C-O)$ vibrational bands at 1913 and $1796 \mathrm{~cm}^{-1}$ in dichloromethane solution. The crystalline compounds $\mathrm{Cp}^{*} \mathrm{M}(\mathrm{CO})_{3} \mathrm{H}(\mathrm{M}=\mathrm{W}$, Mo ) can be easily purified by sublimation. The orange $\mathrm{Cp}^{*} \mathrm{WCl}_{4}$ and purple $\mathrm{Cp}{ }^{*} \mathrm{MoCl}_{4}$ complexes are barely soluble in organic solvents.

### 2.1.2. Dinuclear Chlorido Bridged Molybdenum(IV,IV) Complex

The chlorido bridged molybdenum(IV,IV) complex $\left[\mathrm{Cp}^{*} \mathrm{MoCl}_{3}\right]_{2}$ (1-1) was obtained by one-electron reduction of $\mathrm{Cp}^{*} \mathrm{MoCl}_{4}$ with amalgamated sodium as described by Poli. ${ }^{94}$ (see Reaction Scheme 2.2)

Reaction Scheme 2.2: Synthesis of dinuclear chlorido-bridged molybdenum(IV,IV) complex.

To avoid formation of $\left[\left(\mathrm{Cp}^{*} \mathrm{MoCl}_{2}\right)_{2}\right]$, the addition of NaHg to $\mathrm{Cp}^{*} \mathrm{MoCl}_{4}$ has to be carefully controlled. The olive green chlorido bridged molybdenum(IV,IV) complex 1-1 is extremely air sensitive and insoluble in innocent solvents, such as toluene. The ${ }^{1} \mathrm{H}$ NMR spectrum of the obtained paramagnetic compound 1-1 in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ shows a broad signal at $\delta=-4.19 \mathrm{ppm}\left(\omega_{1 / 2}=42.3 \mathrm{~Hz}\right)$.

### 2.2. Anionic Tungsten(IV) and Molybdenum(IV) Complex

To improve the solubility of the starting material, $\mathrm{Cp}^{*} \mathrm{WCl}_{4}$ was reduced with half equivalent of TDAE in the presence of bis(triphenylphosphoranylidene)ammonium chloride ( PPNCl ). The chemical structure of PPNCl is shown in Figure 2.1.
$\mathrm{PPN}^{+}$assists the isolation of the reduced anion and forms a crystalline salt which is otherwise difficult to crystallize. The brown anionic tungsten $(I V)$ compound $\operatorname{PPN}\left[\mathrm{Cp}^{*} \mathrm{WCl}_{4}\right]$ (1-2) is obtained in good yield of $83 \%$ (see Reaction Scheme 2.3). This paramagnetic compound is well solu-

Figure 2.1.: Structure of PPNCl. ble in polar organic solvents. A broad singlet is observed by proton NMR spectroscopy at 6.84 ppm in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ attributed to the Cp * ligand at room temperature.

Reaction Scheme 2.3: Synthesis of the half-sandwich tungstate(IV) complex 1-2.

The synthesis of Complex $\operatorname{PPN}\left[\mathrm{Cp}^{*} \mathrm{MoCl}_{4}\right]$ was adopted from the procedure described by Poli. ${ }^{94}$ The dinuclear chlorido bridged molybdenum(IV,IV) complex was mixed with PPNCl to give the green paramagnetic molybdate $(I V)$ compound $\operatorname{PPN}\left[\mathrm{Cp}^{*} \mathrm{MoCl}_{4}\right]$ (1-3) with a yield of $89 \%$ (see Reaction Scheme 2.4). The ${ }^{1} \mathrm{H}-$ NMR spectrum of complex 1-3 showed a broad singlet at - 13.96 ppm in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ at room temperature.

Reaction Scheme 2.4: Synthesis of the half-sandwich molybdate(IV) complex 1-3.

### 2.3. Bidentate N -donor Ligand Adducts of Tungsten(IV) and Molybdenum(IV)

### 2.3.1. Synthesis of $d p q-W^{I V}(2-a)$

The bidentate dpq ligand was employed to synthesize the monomeric chlorido half-sandwich tungsten complex $\left[\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq}) \mathrm{Cl}_{3}\right]$ (2-a). The dpq substituted halfsandwich tungsten(IV) complex 2-a was obtained in good yield (89\%) from reaction of $\operatorname{PPN}\left[\mathrm{Cp}^{*} \mathrm{WCl}_{4}\right]$ with the dpq ligand as shown in Reaction Scheme 2.5.

Reaction Scheme 2.5: Synthesis of the dpq substituted half-sandwich tungsten(IV) trichlorido complex $\left[\mathrm{Cp} * \mathrm{~W}(\mathrm{dpq}) \mathrm{Cl}_{3}\right]$ (2-a).

9

Figure 2.2.: ${ }^{1} \mathrm{H}-\mathrm{NMR}$ Spectrum of complex $\left[\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq}) \mathrm{Cl}_{3}\right](2-\mathrm{a})$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ at 300 MHz . The inlay shows the ${ }^{1} \mathrm{H}$-NMR Spectrum of the free dpq ligand in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$.

The mononuclear half-sandwich dpq-W ${ }^{I V}$ complex 2-a has a blueish purple color and is highly insoluble in organic solvents. The proton NMR spectrum of 2-a presented in Figure 2.2 shows a downfield shift of the attached dpq ligand compared to the free ligand. The ${ }^{1} \mathrm{H}$-NMR spectrum revealed three doublets of doublets ( $d \boldsymbol{d}$ ) at $9.67,9.36$ and 8.08 ppm for the protons in para, ortho and meta positions respectively, consistent with the $C_{s}$ symmetry of 2-a as a facial isomer. The electron impact ionization mass spectrum of 2-a showed the highest mass of $\mathrm{m} / \mathrm{z}=656$ for the molecular ion $[2-\mathrm{a}]^{+}$. The purity of product $\mathbf{2 - a}$ was evidenced by elemental analysis.

### 2.3.2. Synthesis of dpphen-W ${ }^{I V}$ (2-b)

The diphenyl substituted phenanthroline ligand, 4,4'-diphenyl phenanthroline (dpphen), was used to increase the donor ability and extend the conjugated system of the N -donor type molecule. The desired dpphen substituted tungsten(IV) tri-chlorido complex $\left[\mathrm{Cp}{ }^{*} \mathrm{~W}(\mathrm{dpphen}) \mathrm{Cl}_{3}\right]$ (2-b) was synthesized in a good yield of $84 \%$ (see Reaction Scheme 2.6). The structure was confirmed by the proton NMR spectroscopy, mass spectrometry, elemental analysis and X-ray crystallography (see below).

Reaction Scheme 2.6: Synthesis of dpphen half-sandwich tungsten(IV) tri-chlorido complex $\left[\mathrm{Cp}^{*} \mathrm{~W}(\right.$ dpphen $\left.) \mathrm{Cl}_{3}\right]$ (2-b).

The green compound dpphen- $W^{I V}(2-b)$ is moderately soluble in polar organic solvents. Slightly broadened signals were observed in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum for this 18 electron $d^{2}$-configured compound (Figure 2.3). The ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of complex 2-b showed a singlet at 8.08 ppm for protons in position 7 and two sets of doublets at 9.31 and 7.88 ppm for the protons in the ortho and meta positions (position 2 and 3) respectively.* This provided evidence for a $C_{s}$ symmetrical

[^0]

Figure 2.3.: ${ }^{1} \mathrm{H}$-NMR Spectrum of complex $\left[\mathrm{Cp}{ }^{*} \mathrm{~W}\right.$ (dpphen) $\left.\mathrm{Cl}_{3}\right]$ (2-b) in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ at 200 MHz . The inlay shows the ${ }^{1} \mathrm{H}$-NMR Spectrum of the free dpphen ligand in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$.
structure and the existence of a facial isomer. The aromatic proton resonances of the coordinated dpphen ligand were shifted to downfield with regard to the free ligand.

## X-ray crystal structure of 2-b

Single crystals of complex 2-b suitable for X-ray crystal structural analysis were obtained from $\mathrm{Et}_{2} \mathrm{O} / \mathrm{DCM}$ solution and unambiguously confirmed the structure of the facial isomer. (see Figure 2.4) Selected bond lengths and angles of complex dpphen- $W^{I V}$ are given in Table 2.1. The data collection parameters are listed in the Appendix.

The structure of this tungsten( $I V$ ) tri-chlorido complex can be described as a pseudo-octahedral geometry with the $\mathrm{Cp}^{*}$ ligand occupying one co-ordination site. The equatorial plane, which includes two nitrogen atoms of the ligand dpphen ( $\mathrm{N} 1, \mathrm{~N} 2$ ) and two Cl ligands, Cl 2 and Cl 3 , bends towards Cl 1 in the trans position of the Cp* ligand. The C11-W1-Z1 angle amounts to $176.20^{\circ}$.* The W1-Z1

[^1]

Figure 2.4.: Crystal structure of complex 2-b (Ortep-representation; 50\%). For reasons of clarity, hydrogen atoms and the co-crystallized dichloromethane solvent molecule are not shown.

[^2]distance ( $2.016 \AA$ ) in this half-sandwich tri-chlorido $\mathrm{W}^{I V}$ complex is significantly shorter than in $\mathrm{Me}_{2} \mathrm{bpy}$ substituted complex $\left[\left(\eta^{5}-\mathrm{C}_{5} \mathrm{Me}_{4} \mathrm{Et}\right) \mathrm{W}\left(\mathrm{Me}_{2} \mathrm{bpy}\right) \mathrm{Cl}_{3}\right](2.20$ $\AA$ ). A slight distortion of the $\mathrm{Cp}^{*}$ ring towards a $\eta^{3}$ ligand coordination was no-
ticed. The $\eta^{3}$-hapticity motif incorporating carbon atoms $\mathrm{C} 1, \mathrm{C} 2$ and C 5 is notable from short W-C bonds of 2.24-2.35 A while long W-C distances of 2.42-2.50 $\AA$ are observed for the ring atoms C3 and C4. The methyl groups of the Cp* ligand are bending out of the Cp-ring plane opposite to the equatorial plane. It is noteworthy that the bond length of Cl1-W1 $(2.5449 \AA$ ) is significantly longer than the Cl2-W1 ( $2.4728 \AA$ ) and Cl3-W1 ( $2.4579 \AA$ ) distances. The phenyl substituents of the dpphen ligand are twisted out of the penantroline plane by $+42.6^{\circ}$ and $-51.4^{\circ}$ respectively. Slightly bigger torsion angles ( $55.1^{\circ}$ and $50.2^{\circ}$ ) were found in iridium complex $\left[\operatorname{Ir}(\mathrm{epqc})_{2}(\mathrm{dip})\right]^{+} .{ }^{110}$

### 2.3.3. Synthesis of $(\mathrm{COOMe})_{2} \mathrm{bpy}-\mathrm{W}^{I V}(2-\mathrm{c})$

The previously established Hammett correlation for the redox potentials of the bipy substituted complexes $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}\left(\mathrm{R}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right]^{2+}\left(\mathrm{R}=\mathrm{NMe}_{2}, \mathrm{Me}, \mathrm{H}, \mathrm{Cl}\right)$ revealed that more electron withdrawing R substituents lead to higher oxidation potentials of the ditungsten complexes. For the even more electron deficient $\mathrm{R}_{2}$ bpy ligand with $\mathrm{R}=\mathrm{COOMe}$ substituents, a potential of +0.68 V (vs. NHE) should be accessible, hence a higher potential as a water oxidation catalyst is anticipated. There is evidence that rhenium bipyridyl $\mathrm{CO}_{2}$ reduction catalysts covalently attached to a $\mathrm{TiO}_{2}$ surface through carboxylate groups display increased photocatalytic reductive ability. ${ }^{111}$ A carboxylate functionalized dinuclear tungsten oxo-bridged complex bonded to a $\mathrm{TiO}_{2}$ semiconductor surface could serve as the reaction center by acting as a trap for excited electrons.

Synthetic access to the desired complex was achieved by reaction of the corresponding $4,4^{\prime}$-dicarboxylate bipy ligand with $\mathrm{PPN}\left[\mathrm{Cp}^{*} \mathrm{WCl}_{4}\right]$. At room temperature, an unknown paramagnetic product along with unseparated side products was obtained. Due to the carboxylate group, the solubility of the obtained complexes were high in both polar and non-polar solvents, which hampered the isolation of the desired pure compound. In the product, unshifted $v(C O)$ band compared to the free ligand $\left(1732 \mathrm{~cm}^{-1}\right)$ was observed in the infrared (IR) spectrum.

In order to access complex $\mathrm{Cp}^{*} \mathrm{~W}\left(\mathrm{COOMe}_{2} \mathrm{bpy}\right) \mathrm{Cl}_{3}(2-\mathrm{c})$, the reaction temperature was risen to $100^{\circ} \mathrm{C}$ for two days (Reaction Scheme 2.7). A further color change was observed: in acetonitrile from brown to dark purple and in dichloromethane from brown to dark blue. The ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectroscopy proved that the two differently colored compounds are identical. The IR spectrum of this product displays

Reaction Scheme 2.7: Synthesis of (COOMe) ${ }_{2}$ bpy substituted half-sandwich tungsten $(I V)$ tri-chlorido complex 2-c in elevated temperature.
two $v(C O)$ bands of strong intensity at wavenumbers 1713 and $1731 \mathrm{~cm}^{-1}$. The ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum was hard to interpret, suggesting a low symmetrical structure. This was confirmed by X-ray diffraction. Apparently hydrogen elimination from a Cp* methyl group and the ortho-position of the bpy ligand is enforced by the high temperatures.

## X-ray crystal structure of 2-c

Suitable single crystals of complex 2-c for X-ray diffraction were obtained from a diluted filtered solution of acetonitrile after high temperature reaction. The refined crystal structure presented in Figure 2.5 contains an ester group, which is rotationally disordered over two split positions. Selected bond lengths and angles are listed in Table 2.2.

The crystal structure of complex $(\mathrm{COOMe})_{2} \mathrm{bpy}-\mathrm{W}^{I V}$ displays a pseudo-octahedral geometry. It is a meridional isomer with three Cl and one N occupying the equatorial plane. It is noteworthy that dihydrogen was apparently eliminated between $\mathrm{Cp}^{*}$ and (COOMe) ${ }_{2}$ bpy ligands. Bond C1-C6 is bent towards the (COOMe) ${ }_{2}$ bpy ligand (C6 atom is 0.1329 A below the Cp plane), while the other four methyl groups of $\mathrm{Cp}{ }^{*}$ ligand are pointing away from the equatorial plane. The centroid of the Cp ring, Z1, and W1, N2 is forming an angle of $172.87^{\circ}$ which is $3.33^{\circ}$ smaller than the facial isomer. The three $\mathrm{W}-\mathrm{Cl}$ bond lengths are essentially identical and in the narrow range of 2.4392 to $2.4538 \AA$. The W1-N1 bond in the equatorial plane is rather short $(2.1108 \AA)$ while the W1-N2 bond in the trans position of Cp* is elongated to $2.2358 \AA$.

Figure 2.5.: Crystal structure of complex 2-c (Ortep-representation; 50\%). For reasons of clarity, hydrogen atoms are not shown.

[^3]
### 2.3.4. Synthesis of dpq-Mo ${ }^{I V}$ (3-a)

The molybdenum analogue of the half-sandwich tungsten $(I V)$ tri-chlorido complex $\left[\mathrm{Cp}^{*} \mathrm{Mo}(\mathrm{dpq}) \mathrm{Cl}_{3}\right](3-\mathbf{a})$ was synthesized in a similar manner by reaction of
half-sandwich molybdate(IV) complex 1-3 with dpq ligand in DCM solution (see Reaction Scheme 2.8).

Reaction Scheme 2.8: Synthesis of the molybdenum $(I V)$ half-sandwich tri-chlorido complex $\mathrm{Cp}^{*} \mathrm{Mo}(\mathrm{dpq}) \mathrm{Cl}_{3}(3-\mathrm{a})$.

The purple product 3-a is obtained in a good yield of $89 \%$ and is also rather insoluble in organic solvents. For a very low concentrated solution of complex $\left[\mathrm{Cp}^{*} \mathrm{Mo}(\mathrm{dpq}) \mathrm{Cl}_{3}\right]$ in $\mathrm{CD}_{3} \mathrm{CN}$, an ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum was recorded, Figure 2.6.

$$
9+10
$$

Figure 2.6.: ${ }^{1} \mathrm{H}-\mathrm{NMR}$ Spectrum of complex $\left[\mathrm{Cp}{ }^{*} \mathrm{Mo}(\mathrm{dpq}) \mathrm{Cl}_{3}\right](\mathbf{3 - a})$ in $\mathrm{CD}_{3} \mathrm{CN}$ at 300 MHz . The inlay corresponds to the ${ }^{1} \mathrm{H}$-NMR Spectrum of the free dpq ligand in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$.

Comparison of the ${ }^{1} \mathrm{H}$-NMR spectra of the fac-tungsten analogue $\left[\mathrm{Cp}{ }^{*} \mathrm{~W}(\mathrm{dpq}) \mathrm{Cl}_{3}\right.$ ] (2-a) and compound 3-a revealed that the tri-chlorido $\mathrm{Mo}^{I V}$ complex has apparently a meridional structure. The protons $\mathrm{H}_{[2]}$ and $\mathrm{H}_{[16]}$ of the dpq ligand are diastereotopic and appear as doublets at $\delta=9.10$ and 8.80 ppm in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum. The protons $\mathrm{H}_{[3]}$ and $\mathrm{H}_{[15]}$ are overlapping (two dd close to 8.20 ppm ). Peaks for protons $\mathrm{H}_{[4]}$ and $\mathrm{H}_{[14]}$ are very close in chemical shift, while the peaks for protons $\mathrm{H}_{[9]}$ and $\mathrm{H}_{[10]}$ has the same chemical shifts.

### 2.3.5. Synthesis of ${ }^{t} \mathrm{Bu}_{2} \mathbf{b p y - M o}{ }^{I V}$ (3-d)

The molybdenum tri-bromido analogue of the bpy substituted half-sandwich tungsten(IV) complex CpMo (bipy) $\mathrm{Br}_{3}$ was published in $1966 .{ }^{112}$ The related halfsandwich tri-chlorido complex $\mathrm{Cp}{ }^{*} \mathrm{Mo}\left(\mathrm{R}_{2} \mathrm{bpy}\right) \mathrm{Cl}_{3}$ were obtained by reaction of dinuclear chlorido bridged molybdenum $(I V, I V)$ complex 1-1 with the $\mathrm{R}_{2}$ bpy ligand $\left(\mathrm{R}=\mathrm{Me}, \mathrm{NMe}_{2},{ }^{t} \mathrm{Bu}\right)$. The resulting complexes $\mathrm{Cp}{ }^{*} \mathrm{Mo}\left(\mathrm{Me}_{2} \mathrm{bpy}\right) \mathrm{Cl}_{3}$ (brown) and $\mathrm{Cp}^{*} \mathrm{Mo}\left(\mathrm{NMe}_{2} \mathrm{bpy}\right) \mathrm{Cl}_{3}$ (red) are barely soluble in any solvents tested. Only the ${ }^{t} \mathrm{Bu}_{2}$ bpy substituted complex $\mathrm{Cp}{ }^{*} \mathrm{Mo}\left({ }^{t} \mathrm{Bu}_{2} \mathrm{bpy}\right) \mathrm{Cl}_{3}(3-\mathrm{d})$, which is brown in color, is slightly soluble in dichloromethane. (see Reaction Scheme 2.9)

Reaction Scheme 2.9: Synthesis of molybdenum(IV) half-sandwich tri-chlorido complex $\mathrm{Cp}{ }^{*} \mathrm{Mo}\left({ }^{(t} \mathrm{Bu}_{2} \mathrm{bpy}\right) \mathrm{Cl}_{3}(3-\mathrm{d})$.

The ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of complex 3-d in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ reveals a strongly paramagnetic behaviour ( $\delta=2.24 \mathrm{ppm}$ for $\mathrm{Cp}^{*}$ protons at RT). A down-field shift of the three aromatic bipyridine protons over the free ligand and a broad signal for the Cp * protons at $\delta=2.24 \mathrm{ppm}\left(\omega_{1 / 2}=184 \mathrm{~Hz}\right)$ were detected. Tungsten (IV) and molybdenum (IV) complexes have a $d^{2}$-configuration, thus can be present as low-spin or high-spin compounds. Based on the broad signals observed in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum, complex ${ }^{t} \mathrm{Bu}_{2}$ bpy- $\mathrm{Mo}^{I V}$ (3-d) is considered as a high-spin paramagnetic ( $S=1$ ) compound.

## 3. Dinuclear $\mu$-Oxo-Bridged Tungsten Half-Sandwich Complexes

The chemistry of novel dinuclear $\mu$-oxo-bridged tungsten $(I V, I V)$ half-sandwich complexes with substituted bipyridyl ligands was developed by Cremer. ${ }^{83}$ To create more significant charge separation as well as photosensitizing metal centers, the bidentate N -donor ligands dpq and dpphen were employed to synthesize the dimeric tungsten(IV,IV) complexes. The synthetic, spectral and electrochemical study of dinuclear $\mu$-oxo-bridged tungsten $(I V, I V)$ half-sandwich complexes $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(4-\mathbf{a})$ and $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpphen})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(4-\mathrm{b})$ is described in this chapter.

### 3.1. Synthesis of the Complexes dpq- $W^{I V} W^{I V}(4-a)$ and dpphen- $W^{I V} W^{I V}(4-b)$

The dpq and dpphen substituted half-sandwich ditungsten $(I V, I V)$ oxo-complexes of $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(4-\mathbf{a})$ and $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpphen})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(4-\mathrm{b})$ were obtained in $67 \%$ and $76 \%$ yield respectively by hydrolysis of the mononuclear half-sandwich tungsten (IV) halido complexes. After neutralizing with $\mathrm{NaHCO}_{3}$ in solid state, the products were precipitated by addition of $\mathrm{NH}_{4} \mathrm{PF}_{6}$ (see Reaction Scheme 3.1). The raw products were then extracted with DCM and recrystallized from $\mathrm{Et}_{2} \mathrm{O} / \mathrm{DCM}$.

Reaction Scheme 3.1: Synthesis of $\mu$-oxo-bridged tungsten( $I V, I V$ ) half-sandwich complexes of $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(4-\mathbf{a})$ and $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\text { dpphen })(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(4-\mathbf{b})$.

The reddish purple complex 4-a is well soluble in polar solvent like DCM and ACN, sparingly soluble in THF and nonpolar organic solvents. The ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of the dpq-W ${ }^{I V} \mathrm{~W}^{I V}$ compound is consistent with the $C_{2 v}$-symmetry of 4-a and shows high-field shifts for all protons with regard to the mononuclear reactant 2-a. Two dimensional ${ }^{13} \mathrm{C}-{ }^{1} \mathrm{H}-\mathrm{NMR}$ methods such as HSQC and HMBC techniques were employed to assign the observed signals. The desired compound 4-a was verified by $\mathrm{FAB}^{+}$mass spectrometry, in which the major peak was found at $\mathrm{m} / \mathrm{z}=567.1$ for the doubly charged cation $\left[\left(\mathrm{Cp}{ }^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]^{2+}$ with the expected isotopic pattern, and elemental analysis (data presented in Experimental detail section). The dimeric structure was unambiguously confirmed by X-ray crystal structure analysis (see below).

The salt $\mathrm{Li}\left[\mathrm{Al}(\mathrm{pftb})_{4}\right]$ is a useful precursor for introducing the weakly coordinating $\left[\mathrm{Al}(\mathrm{pftb})_{4}\right]^{-}$anion into various other salts by metathesis (Reaction Scheme 3.2). For example, complex $\left[\left(C p^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]\left[\mathrm{Al}(\mathrm{pftb})_{4}\right](4-\mathrm{a} 1)$ was obtained

$\mathbf{L i}\left[\mathrm{Al}(\mathrm{pftb})_{4}\right]$

Reaction Scheme 3.2: Metathesis reaction of complex $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(4-\mathrm{a})$ with $\mathrm{Li}\left[\mathrm{Al}(\mathrm{pftb})_{4}\right]$.
by stirring of complex 4 -a with two equivalents of $\mathrm{Li}\left[\mathrm{Al}(\mathrm{pftb})_{4}\right]$ in THF for two hours. The ${ }^{19} \mathrm{~F}$ resonance of the anionic moieties consist of a doublet for $\left[\mathrm{PF}_{6}\right]^{-}$at $72.87 \mathrm{ppm}\left({ }^{1} J_{F P}=707 \mathrm{~Hz}\right)$ and a singlet for $\left[\mathrm{Al}(\mathrm{pftb}){ }_{4}\right]^{-}$at -75.98 ppm in $\mathrm{CD}_{3} \mathrm{CN}$, and the integration fits to $6: 36$ for $\left[\mathrm{PF}_{6}\right]^{-}:\left[\mathrm{Al}(\mathrm{pftb})_{4}\right]^{-}$. In order to obtain complex with only $\left[\mathrm{Al}(\mathrm{pftb})_{4}\right]^{-}$counter anions, i.e. $\left[\left(\mathrm{Cp}{ }^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{Al}(\mathrm{pftb})_{4}\right]_{2}$ (4-a2), a small amount of acetonitrile was added to dissolve the reactant 4-a. A singlet attributed to the $\left[\mathrm{Al}(\mathrm{pftb})_{4}\right]^{-}$anion was detected in ${ }^{19} \mathrm{~F}$-NMR spectrum at - 77.77 ppm . Complex 4 -a2 with the weakly coordinating $\left[\mathrm{Al}(\mathrm{pftb})_{4}\right]^{-}$counter anions is more soluble in less polar THF solvent.

## X-ray crystal structure of 4-a

Single crystals suitable for X-ray diffraction were obtained by diffusion of $\mathrm{Et}_{2} \mathrm{O}$ into a DCM solution of complex 4-a. Figure 3.1 depicts the molecular structure of $4-\mathrm{a}$. The most important bond lengths and angles are listed in Table 3.1.

Figure 3.1.: Crystal structure of complex 4-a (Ortep-representation; 50\%). For reasons of clarity, hydrogen atoms and two $\left[\mathrm{PF}_{6}\right]^{-}$anions are not shown here.

The molecule is located on a special position. One half of the molecule, which consists of a $C p^{*} W(O)(d p q)$ unit, was refined. The dinuclear complex 4 -a displays a cis geometry for the two Cp * ligands. Each tungsten metal center adopts a square pyramidal coordination sphere, in which the Cp * ligand occupies one coordination site, which is located in apical position of the pyramidal structure,

Figure 3.2.: The definitions of angles $\alpha$ and $\beta$ : $\alpha$ is the angle between two bidentate N donor ligand planes, $\beta$ is the torsion angle between two bidentate N -donor ligands.

${ }^{a}$ estimated standard deviations in parentheses
${ }^{b} \mathrm{Z} 1$ is the ring centroid of carbon atoms C1-C5.
${ }^{c} \alpha$ is the angle between two dpq ligand planes.
${ }^{d} \beta$ is the torsion angle between two dpq ligands.
four atoms ( $\mathrm{N} 1, \mathrm{~N} 2, \mathrm{O} 1, \mathrm{O} 1 \_2$ ) are placed at the corners of the square base and the tungsten center is above the basal plane of the pyramidal. The distance between the two tungsten centers amounts to $2.736 \AA$, the bond is bridged by two oxygen atoms forming a puckered $\mathrm{W}_{2} \mathrm{O}_{2}$ ring. The distance from W 1 to the carbon atoms of the Cp ring are in a narrower range of 2.311 to $2.431 \AA$ compared to the
monomeric complexes ( 2.238 to $2.497 \AA$ for 2-b and 2.223 to $2.477 \AA$ for $\mathbf{2 - c}$ ), the $\alpha$ and $\beta$ angles are defined in Figure 3.2. Two dpq ligand planes are nearly coplanar with a small $\alpha$ angle of $11^{\circ}$ (see footnote of Table 3.1), which is much smaller than the values in $\mathrm{R}_{2}$ bpy substituted dinuclear complexes $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}\left(\mathrm{R}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right]^{2+}$ $\left(\alpha=17.8^{\circ}\right.$ for $\mathrm{R}=\mathrm{Me}, \alpha=35.6^{\circ}$ for $\left.\mathrm{R}={ }^{t} \mathrm{Bu}\right) . .^{83}$ The rings are slightly eclipsed, the torsion angle of $8.8^{\circ}$ between the two planes of the dpq ligands is also observed. The N1-W1-W1_2 angle is close to $90^{\circ}\left(90.82^{\circ}\right)$ while the N2-W1-W1_2 angle are lager by $6.44^{\circ}$. The square pyramidal geometry of complex $4-\mathrm{a}$ is slightly distorted as can be seen by inspection of various axial site -metal - basal site angles, which amount to $109.50^{\circ}$ for Z1-W1-N2, $111.35^{\circ}$ for Z1-W1-O1, $114.16^{\circ}$ for Z1-W1-N1 and $115.91^{\circ}$ for Z1-W1-O1_2.

The blue complex 4-b is well soluble in DCM and ACN, slightly soluble in THF and insoluble in nonpolar organic solvents. Structure characterization of complex 4-b by ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectroscopy was performed in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$, which showed high-field shifts for all proton signals with regard to the monomer complex 2b. Two-dimensional NMR measurements (COSY, HSQC and HMBC) were also performed to assist the peak assignment. The structure of the desired bimetallic complex was unambiguously confirmed by mass spectrometry, elemental and X-ray crystal analysis.

## X-ray crystal structure of 4-b

A single crystal suitable for X-ray diffraction was obtained by diffusion of diethyl ether into a DCM solution of complex 4-b. The crystal structure of the complex dication and anions were well resolved (see Figure 3.3), the co-crystallized solvent molecules were refined as $0.33 \mathrm{DCM}, 0.45$ and 0.22 of two independent $\mathrm{Et}_{2} \mathrm{O}$ molecules. Important structure information of complex 4-b is listed in Table 3.2.

The geometry around the tungsten centers are essentially square pyramidal and the two dpphen ligands are arranged in a cis orientation. The observed W1-N1, W1-N2 bond lengths ( $2.1507,2.1545 \AA$ ) for 4-b are smaller than the values for the mononuclear complex 2-b, while the distance for the W2 center (W2-N3 2.1636, W2-N4 2.1669) are comparable with the distance in 2-b. The distance for the two tungsten centers ( $2.736 \AA$ ) in dpphen- $W^{I V} W^{I V}$ equals to the distance in the corresponding tungsten centroids distance in complex dpq- $W^{I V} W^{I V}(4-a)$. The angle formed by the planes of the phenanthroline unit of the dpphen ligand $(\alpha)$ is

Figure 3.3.: Crystal structure of complex 4-b (Ortep-representation; 50\%). For reasons of clarity, two $\left[\mathrm{PF}_{6}\right]^{-}$anions, the hydrogen atoms and the co-crystallized solvent molecules are not shown.
quite large $\left(16.46^{\circ}\right)$, presumably due to steric repulsion between the phenyl substituents. The torsion angle between the two dpphen ligands is $11.6^{\circ}$, which is also larger than the torsion angle between the dpq ligands in complex 4-a. The angle between the phenanthroline unit and the phenyl substituents of the dpphen ligand coordinated to W 1 are only $+36.7^{\circ}$ and $-36.8^{\circ}$, while larger angles of $+53.8^{\circ}$ and $+58.6^{\circ}$ are observed between the phenyl substituents and the phenanthroline unit of the dpphen ligand coordinated to the tungsten metal center W2.

[^4]
### 3.2. Attempted Chemical Oxidation of 4-a

The oxidation of bis- $\mu$-oxo ditungsten $(I V / I V)$ complex 4 -a was carried out by adding a stoichiometric amount of oxidant $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]\left[\mathrm{PF}_{6}\right], \mathrm{Ag}\left[\mathrm{PF}_{6}\right]$ or $[\mathrm{NO}]\left[\mathrm{PF}_{6}\right]$ which have formal potentials $0 \mathrm{~V}, 0.87 \mathrm{~V}$ in $\mathrm{ACN}, 0.65 \mathrm{~V}$ in DCM respectively vs the $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+} /\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]$ couple. ${ }^{113}$ The oxidized compound could only be isolated
for the reaction with the stronger oxidant $[\mathrm{NO}]\left[\mathrm{PF}_{6}\right]$ in acetonitrile (see Reaction Scheme 3.3).

5-a

5-a1

5-a2

Reaction Scheme 3.3: Attempted chemical oxidation of complex 4-a with one and two equivalents of nitrosonium salt in acetonitrile.

Through oxidation of the purple complex dpq- $\mathrm{W}^{I V} \mathrm{~W}^{I V}(4-a)$ with one equivalent of $[\mathrm{NO}]\left[\mathrm{PF}_{6}\right]$ in acetonitrile, the yellow bis- $\mu$-oxo ditungsten $(I V / V)$ complex $\left[\left(C p^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{3}(5-a 1)$ was obtained and verified by ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectroscopy (see Figure 3.4). By comparison of the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra for $5-\mathrm{a} 1$ and the reactant $4-\mathrm{a}$, the proton resonance for $\mathrm{Cp}^{*}$ is shifted from 1.61 ppm to 1.58 ppm and all proton peaks for the attached dpq ligand (9.90 ppm for $\mathrm{H}_{[4]}, 9.27$ ppm for $\mathrm{H}_{[9]}+\mathrm{H}_{[2]}, 8.34 \mathrm{ppm}$ for $\mathrm{H}_{[3]}$ ) are strongly shifted down-field*. It can be seen that all peaks are slightly broadened indicating paramagnetism of the ditungsten $(I V / V)$ complex 5-a1.

Through oxidation with two equivalents $[\mathrm{NO}]\left[\mathrm{PF}_{6}\right]$ in acetonitrile, the dimeric structure of complex 4 -a breaks down to the mononuclear complex and acetonitrile is coordinated to the metal center. A single crystal structure verified the brown product as $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})\left(\mathrm{NCCH}_{3}\right)_{2}(\mathrm{OH})\right]\left[\mathrm{PF}_{6}\right]_{2}(5-\mathrm{a})\right.$. Comparison of the

[^5]

Figure 3.4.: ${ }^{1} \mathrm{H}-\mathrm{NMR}$ Spectrum of complex 4-a (brickred), 5-a1 (green) and 5-a (blue) in $\mathrm{CD}_{3} \mathrm{CN}$ at 400 MHz . The inlay is scaled up view of the attached dpq ligand.
${ }^{1} \mathrm{H}$-NMR spectra for the dimeric complex 4-a and the monomeric compound 5-a reveals that the proton resonance for the $\mathrm{Cp}^{*}$ ligand is shifted from 1.61 ppm to 1.92 ppm , furthermore, a down-field shift of the proton resonances for the dpq ligand was also detected. The proton attached to the oxygen atom was not detected by proton NMR spectrum, presumably due to H/D exchange with the deuterated solvent. To avoid solvent coordination at the final product, the polar solvent nitromethane was employed for this reaction, but the desired ditungsten $(V / V)$ complex (5-a2) could not be obtained by the solvent variation.

## X-ray crystal structure of 5-a

Single crystals of complex $\left[\left(\mathrm{Cp}{ }^{*} \mathrm{~W}(\mathrm{dpq})\left(\mathrm{NCCH}_{3}\right)_{2}(\mathrm{OH})\right]\left[\mathrm{PF}_{6}\right]_{2}\right.$ (5-a) were easily obtained by crystallization from $\mathrm{Et}_{2} \mathrm{O} / \mathrm{CH}_{3} \mathrm{CN}$ solution. Figure 3.5 depicts the X ray crystal structure of 5-a. The molecular cation is well refined, while the $\left[\mathrm{PF}_{6}\right]^{-}$ anions are disordered over two positions. The cavity between molecules is filled with solvent molecules, which could not be well resolved. Selected bond lengths and angles of the dication are listed in Table 3.3.

Figure 3.5.: Crystal structure of complex 5-a (Ortep-representation; 50\%). For reasons of clarity, hydrogen atoms, two $\left[\mathrm{PF}_{6}\right]^{-}$anions and the co-crystallized solvent molecule are not shown.

Table 3.3.: Selected bond lengths [ $\AA \AA$ ] and angles [ ${ }^{\circ}$ ] of complex 5-a. ${ }^{a}$

| W1-N1 | $2.169(4)$ | W1-N2 | $2.176(4)$ |

| W1-C4 | $2.278(5)$ | W1-C5 | $2.361(5)$ |
| W1-Z1 ${ }^{b}$ | 2.025 |  |  |
|  |  |  |  |
| N1-W1-N2 | $76.64(17)$ | N1-W1-N5 | $92.70(17)$ |
| N1-W1-N6 | $152.39(17)$ | N1-W1-O1 | $76.33(15)$ |
| N2-W1-N5 | $152.07(17)$ | N2-W1-N6 | $91.53(16)$ |
| N2-W1-O1 | $75.99(15)$ | N5-W1-N6 | $86.27(17)$ |
| N5-W1-O1 | $76.41(15)$ | N6-W1-O1 | $76.62(16)$ |
| N1-W1-Z1 | 103.18 | N2-W1-Z1 | 104.31 |
| N5-W1-Z1 | 103.25 | N6-W1-Z1 | 103.89 |
| O1-W1-Z1 | 179.36 |  |  |

[^6]The six-coordinate $\mathrm{W}^{I V}$ is centered in a distorted octahedral configuration with Z1-W1-equatorial ligand atom angles between $103.18^{\circ}$ to $104.31^{\circ}$ and a Z1-W1-O1 angle of $179.36^{\circ}$ ( Z 1 is the ring centroid of the $\mathrm{Cp}{ }^{*}$ ligand). The bond lengths of W1-N5 ( $2.129 \AA$ ) and W1-N6 ( $2.130 \AA$ ) for the coordinated acetonitrile ligands are shorter than the W1-N1 ( $2.169 \AA$ ) and W1-N2 $(2.176 \AA)$ distances for the attached dpq ligand. The W1-O1 bond length of $1.948 \AA$ is substantially longer than typical $\mathrm{W}=\mathrm{O}$ double bonds, which display an average distance of $1.74 \AA .{ }^{114,115}$ Therefore,
the oxygen atom O 1 in complex $\mathbf{5 - a}$ is a hydroxyl group rather than a terminal oxo ligand. The W-O bond length falls into typical range of W-O single bond, which is consistent with the observed diamagnetic behavior. The W-O bond lengths of hydroxyl groups in other complexes were found to be $1.829 \AA$ (with stronger hydrogen bonding with ether), $1.858 \AA$ (with weaker hydrogen bonding to $\mathrm{OTf}^{-}$) in complex $\left[\mathrm{Cp}{ }^{*} \mathrm{~W}(\mathrm{OH})(\mu-\mathrm{S})_{2} \mathrm{RuH}\left(\mathrm{PPh}_{3}\right)_{2}\right]^{+},{ }^{115} 2.064 \AA$ (no hydrogen bonding) in complex $\left[\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{OH})(\mathrm{NO})\left(\eta^{2}-\mathrm{HN}=\mathrm{C}(\mathrm{Me}) \mathrm{CH}=\mathrm{CPh}\right)^{116,117}\right.$ and $1.916 \AA$ in complex trans- $\left[\mathrm{W}(\mathrm{OH})(\mathrm{O})(\text { dppe })_{2}\right]^{+} .{ }^{118}$

### 3.3. Chemical Reduction of 4-a

Due to the extremely high air-sensitivity of the reduced form of bis- $\mu$-oxo ditungsten $(I V / I V)$ complexes, several efforts to prepare the reduced bis- $\mu$-oxo ditungsten(III/III) complex $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right](6-\mathrm{a})$ failed. By carefully handling the solvent purity and removing co-crystallized dichloromethane of the crystalline complex dpq- $W^{I V} W^{I V}(4-a)$, the reduced complex $d p q-W^{I I I} W^{I I I}$ (6-a) was obtained by reaction with two equivalents of sodium naphthalenide. The latter was prepared in situ by stirring naphthalene with an excess amount of freshly cut sodium. (Reaction Scheme 3.4).

Reaction Scheme 3.4: Reduction of complex 4-a with sodium naphthalenide to yield neutral complex $\left[\left(C p^{*} W(d p q)(\mu-O)\right)_{2}\right](6-a)$.

The bluish purple product 6-a was obtained in a good yield of $77 \%$ by extraction with pentane. The identification of complex 6-a rests on the results from NMR spectroscopy, mass spectrometry and X-ray crystal structure analysis. The ${ }^{1} \mathrm{H}$ NMR spectrum of complex 6-a in $\mathrm{C}_{6} \mathrm{D}_{6}$ reveals diamagnetic behavior and exhibits four sets C-H units of the coordinated dpq ligand at $7.84,7.35,6.31$ and 5.62 ppm
with integrations of 4:4:4:4 ratio, the singlet at 1.63 ppm was assigned to the protons of the Cp ${ }^{*}$ ligand coupling pattern. The neutral complex 6-a is soluble in less polar solvents, e.g. THF and even slightly soluble in pentane, but decomposes in polar solvent like DCM. The MALDI-TOF mass spectrum displays the exact isotopic pattern as calculated mass distribution for complex $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]$ with the expected $\mathrm{m} / \mathrm{z}$ at 1134.291.

## X-ray crystal structure of 6-a

Single crystals of complex 6-a suitable for X-ray diffraction were grown in pentane/THF solution at $-32^{\circ} \mathrm{C}$ over long time. Figure 3.6 displays the molecular structure of the neutral complex 6-a. The co-crystallized THF molecule and hydrogen atoms are omitted for clarification. Selected bond lengths and angles are presented in Table 3.4.

Figure 3.6.: Crystal structure of complex 6-a (Ortep-representation; 50\%). For reasons of clarity, hydrogen atoms and the co-crystallized THF solvent molecule are not shown.

In contrast to the crystal structure of the $\mathrm{Me}_{2} \mathrm{bpy}$ substituted ditungsten(IV,IV) complex $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}\left(\mathrm{Me}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right]$, which has a trans arrangement of the Cp * ligands with a flat $\mathrm{W}_{2} \mathrm{O}_{2}$ ring, ${ }^{83}$ the molecular structure of the dpq substituted complex $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right](6-\mathbf{a})$ displays a cis configuration with a puckered $\mathrm{W}_{2} \mathrm{O}_{2}$ ring. The main structure of the neutral complex 6-a shows great resem-

${ }^{c}$ Z2 is the ring centroid of carbon atoms C25-C29.
${ }^{d} \alpha$ is the angle between two dpq ligand planes.
${ }^{e} \beta$ is the torsion angle between two dpq ligands.
blance to the dication of complex 4-a which adopts a square pyramidal coordination sphere for the tungsten centers. However, the W1-O1 (1.9602 Å), W1-O2 $(1.9617 \AA)$ and W2-O1 (1.9633 A) , W2-O2 $(1.9582 \AA)$ bonds are slightly longer than the W-O bond in complex 4-a (1.9554 and $1.9454 \AA$ ), while the W1-W2 bond $(2.71343 \AA)$ is $0.02279 \AA$ shorter in the reduced compound $6-\mathbf{a}$. DFT calculations were performed for the dication complex 4-a and the neutral complex 6-a.

As illustrated in Figure 3.7, the HOMO of complex 4 -a is purely metal based while the HOMO of $\mathbf{6 - a}$ has some bonding character between two dpq ligands, which explains the shorter $\mathrm{W}-\mathrm{W}$ bond in the reduced compound $\mathbf{6 - a}$. The $\alpha$ angle between two dpq ligands is $2.3^{\circ}$ smaller with regard to the cationic species and the torsion angle between the two dpq ligands $(\beta)$ in bis- $\mu$-oxo ditungsten(III/III) complex $\left(1.2^{\circ}\right)$ are remarkably smaller compared to those in bis- $\mu$-oxo ditungsten (IV/IV) complexes ( $11^{\circ}$ ).

HOMO of 4-a

HOMO of 6-a

Figure 3.7: The HOMOs of complexes $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2} \quad(4-\mathbf{a})$ and $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right](\mathbf{6}-\mathbf{a})$.

### 3.4. Comproportionation Reaction between $\mathrm{dpq}-\mathrm{W}^{I V} \mathbf{W}^{I V}$ and dpq- $\mathbf{W}^{I I} \mathbf{W}^{I I I}$

The mixed valence complex dpq- $W^{I V} W^{I I I}(7-a)$ can be obtained by comproportionation reaction of dpq- $W^{I V} W^{I V}(4-a)$ and dpq- $W^{I I I} W^{I I I}(6-a)$ in THF (Reaction Scheme 3.5). The purple complex $\mathrm{dpq}-\mathrm{W}^{I V} \mathrm{~W}^{I I I}$ with the $\left[\mathrm{Al}(\mathrm{pftb})_{4}\right]^{-}$counter anion (7-a2) is paramagnetic and moderately soluble in THF. A broad signal at 10.6 ppm and a singlet at 8.8 ppm were observed in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum in $\mathrm{THF}-\mathrm{d}_{8}$ at room temperature.

7-a2

Reaction Scheme 3.5: Comproportionation reaction of complex dpq-W ${ }^{I V} \mathrm{~W}^{I V}(4-\mathrm{a} 2)$ with $\mathrm{dpq}-\mathrm{W}^{I I I} \mathrm{~W}^{I I I}(6-\mathbf{a})$ to generate the paramagnetic complex dpq-W $\mathrm{W}^{I I I} \mathrm{~W}^{I V}(7-\mathbf{a} 2)$.

## VT-NMR of Complex 7-a2

Figure 3.8 displays the variable temperature proton NMR spectra measured in THF- $\mathrm{d}_{8}$ in the temperature range from 230 to 300 K . The broad peak shifted to the down-field and showed significant broadening when the temperature dropped, while the singlet shifted slightly and also broadened.

The temperature dependence of the paramagnetic shifts showed good agreement with Curie behavior, which confirmed the doublet state of complex dpq-W ${ }^{I I I} W^{I V}$ (see Figure 3.9).

Figure 3.8.: Variable temperature ${ }^{1} \mathrm{H}$-NMR Spectra of complex 7 -a2 in THF-d 8 measured in the temperature range between 230 to 300 k .

Figure 3.9.: Temperature dependence of NMR paramagnetic shift in Figure 3.8.

## X-ray crystal structure of the mixed valence complex 7-a1

Single crystals suitable for X-ray diffraction are separated from the $\mathrm{Et}_{2} \mathrm{O} / \mathrm{ACN}$ solution of complex $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right](7-\mathrm{a} 1)$. Figure 3.10 presents the molecular structure of complex 7-a1. Selected structural parameters of complex 7-a1 are summarized in Table 3.5.

Figure 3.10.: Crystal structure of complex 7-a1 (Ortep-representation; 50\%). For reasons of clarity, hydrogen atoms, one $\mathrm{PF}_{6}$ anion and the co-crystallized solvent ACN molecule are omitted.

The geometry of complex $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]$ is essentially identical to complex $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(4-\mathrm{a})$ and complex $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]$ $(6-\mathbf{a})$. Of these three complexes, the $\alpha$ angle $\left(7.7^{\circ}\right)$ for $7-\mathbf{a} 1$ is the smallest and the $\beta$ angle $\left(6.1^{\circ}\right)$ lies in between. The distance between the two tungsten centers is $2.73231 \AA$ which is close to the distance in complex 4-a.

Table 3.5.: Selected bond lengths $[\AA]$ and -angles $\left[{ }^{\circ}\right]$ of $\mathbf{7 - a 1} .^{a}$

## EPR of Complex 7-a2

X-band ( $\nu \sim 9.5 \mathrm{GHz}$ ) electron paramagnetic resonance spectra of the mixed valence complex 7-a2 were collected using a Bruker Elexsys E500 CW spectrometer at liquid nitrogen temperature as a frozen glass and at room temperature in 2-methyl-tetrahydrofuran.

At a temperature of $\mathrm{T}=97 \mathrm{~K}$, a rhombic lineshape was observed (Figure 3.11). The g-factor of complex dpq- $W^{I V} W^{I I I}$ is anisotropic, the $g$-values are as follows: $\mathrm{g}_{x}=2.00, \mathrm{~g}_{y}=1.98^{*}, \mathrm{~g}_{z}=1.89$. No hyperfine structures to ${ }^{183} \mathrm{~W}(\mathrm{I}=1 / 2,14 \%)$ and ${ }^{14} \mathrm{~N}$ ( $\mathrm{I}=1$, long distance from unpaired electron) were observed.

Figure 3.11.: EPR spectrum of complex 7-a2 in a frozen 2-Methyl-tetrahydrofuran glass.

At room temperature, the observed EPR line of the mixed valence complex 7-a2 becomes broader and weaker (Figure 3.12). The resulting spectra are motionally averaged, and show two peaks corresponding to the $g$-values of $1.95^{*}, 1.89$.

[^8]

Figure 3.12.: EPR spectrum of complex 7-a2 in 2-Methyl-tetrahydrofuran at room temperature.

### 3.5. Spectral Properties

### 3.5.1. Electronic Absorption Spectroscopy of Complexes 4-a and 4-b

The electronic absorption spectrum of complex $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(4-\mathbf{a})$ was recorded in the range of $400-1000 \mathrm{~nm}$ using a 0.82 mM solution in acetonitrile and dichloromethane (Figure 3.13). The strongest absorption band at $535 \mathrm{~nm}\left(\epsilon=11998 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}\right)$ with a shoulder around 630 nm and the lowestenergy electronic transition at $790 \mathrm{~nm}\left(\epsilon=6570 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}\right)$ in ACN are observed in the visible and NIR region respectively.

The observed large extinction coefficients ( $\epsilon=11998$ and $6570 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}$ ) are typical for symmetry allowed charge transfer bands, which normally have large extinction coefficients between 1000 and $50000 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}$. This compares to the intensity of $d$ - $d$ transitions, which are typically small $\left(\epsilon \approx 250 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}\right.$ for $d-d$

Figure 3.13.: Electronic absorption spectrum of complex 4-a in $\mathrm{ACN}(\mathrm{C}=0.82 \mathrm{mM})$ and DCM. Cuvette light pass length is 0.1 cm .
transition in noncentrosymmetric complexes and $\epsilon \approx 1000 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}$ for symmetry allowed transitions). LMCT bands are favored if the metal has low lying vacant orbitals i.e. metal in high oxidation states or if the ligands have lone pairs of relatively high energy e.g. sulphur atoms. The energy gap between the $5 d$ orbitals of the tungsten center and the oxygen centered lone pairs is very large thus LMCT bands from the oxygen lone pairs to the tungsten centers should be in the UV region. In the molecules studied here, LMCT bands attributes to charge transfer from the $\mathrm{Cp}{ }^{*} \pi$ donor ligand to the $\mathrm{W}^{I V}$ metal centers. MLCT bands can be attributed to the electron transfer from the metal based orbital to the empty low lying $\pi^{*}$ orbital $\left(\mathrm{E}_{L U M O}=-2.759 \mathrm{eV}\right.$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$, calculated from electrochemical data, see next section) of the dpq ligand.

In addition, complex 4-a shows a slight red-shift of absorption bands in dichloromethane with respect to ACN. Such solvent-induced shifts are typically observed for charge transfer bands. ${ }^{119-121}$ A change in solvent polarity will show different stabilization effect on the ground and excited states since the polarity of the excited state differs from the ground state.

Therefore, the absorption at 535 and 795 nm can be readily assigned to MLCT bands, which is charge transfer from tungsten $d$ orbital to the $\pi^{*}$ orbital of dpq ligand, and LMCT bands, corresponding to charge transfer from the $\pi$ orbital of $\mathrm{Cp}{ }^{*}$ ligand to the $\pi^{*}$ orbital of the tungsten center.

By comparison with the absorption spectra of complexes containing the same ligand set and metal center, for example, complex $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}\left(\mathrm{Me}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}{ }^{83}$ and complex $\left[\left(C p^{*} W(\text { dpphen })(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}$ (see Figure 1.8 in Chapter 1 and Figure 3.16 in this section respectively), the assignment of the absorption band at 790 nm to LMCT transition $\left(\mathrm{Cp}^{*} \rightarrow \mathrm{~W}\right)$ was conjectured on the position of the absorption around 790 nm . Whether this tentative assignment has a real physical basis or not will be investigated later through TD-DFT calculations (vide infra).

Figure 3.14.: Relative energy of frontier molecular orbital for square pyramidal molecule.

The energy scheme of the orbitals for square pyramidal complexes is presented in Figure 3.14. The metal based vacant orbital $\mathrm{d}_{z^{2}}$ is perturbed by interaction with the low-lying $\pi^{*}$ orbital of the dpq ligand. The metal based degenerate orbitals $\mathrm{d}_{x z}$ and $\mathrm{d}_{y z}$ are elevated by interaction with filled $\pi$ orbitals of the Cp* ligand.

Figure 3.15.: Schematic interaction diagram for two weakly interacting square pyramidal $d^{2}$ complex. Potential low-energy one-electron excitations of ground state

The schematic interaction diagram for two strongly interacting square pyramidal $d^{2}$ configured complex is shown in Figure 3.15. The metal based molecular orbital $\mathrm{d}_{x y}, \mathrm{~d}_{z^{2}}$ levels of the dimer split by the perturbation of the other metal atom. The high lying antibonding degenerate orbitals $\mathrm{d}_{x z}, \mathrm{~d}_{y z}$ and orbital $\mathrm{d}_{x^{2}-y^{2}}$ are not shown in Figure 3.15. The HOMO and LUMO energies of the dimer complex 4-a are calculated from the CV data (cf. below). Based on the experimental data, the
lowest energy transition (HOMO $\rightarrow$ LUMO) should be in the NIR region due to the small HOMO-LUMO energy gap ( 1.05 eV ). As illustrated in Figure 3.15, several MLCT and LMCT bands are expected in the visible and NIR region. MLCT transitions occur due to the possession of several low-lying vacant orbitals of dpq ligand. The LMCT transitions are usually in the ultraviolet region, however, due to the donor ability of the Cp * ligand bind the relatively high oxidation state of the $\mathrm{W}^{I V}$ center, they are anticipated to occur in the visible region.

To investigate the photophysical properties of the dpphen substituted ditungsten $(I V, I V)$ complex $\left[\left(C p^{*} W(\text { dpphen })(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(4-\mathrm{b})$, the electronic absorption spectrum was measured in acetonitrile. The spectrum is shown in Figure 3.16.

Figure 3.16.: Vis-NIR absorbance spectrum of complex 4-b in acetonitrile ( $C=0.80 \mathrm{mM}$ ).

The intense high-energy absorption bands in the UV region can be safely assigned to dpphen ligand based transitions, which are not shown here. The maximum absorption in the visible range is at $\lambda=590 \mathrm{~nm}\left(\epsilon=17469 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}\right)$, which is red shifted due to the donor ability of the phenyl substituents as compared to the dpq substituted complex 4-a. The lower-energy MLCT band at 789 nm has an extinction coefficient of $10841 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}$, found at a similar position for complex dpq-W ${ }^{I V} \mathrm{~W}^{I V}(790 \mathrm{~nm})$.

### 3.5.2. TD-DFT Calculations for Complex 4-a

DFT (density functional theory) calculations were applied with success as a theoretical approach to study the electronic transitions for the $\mathrm{Ru},{ }^{122-124} \mathrm{Re}^{125-128}$ and $\mathrm{Ir}^{129}$ polypyridyl complexes. Therefore, time-dependent DFT (TD-DFT) calculations were carried out also to interpret the photophysical properties of the $\mu$-oxobridged tungsten $(I V, I V)$ half-sandwich complex 4-a.

Figure 3.17 compares the calculated electronic transitions* with the measured electronic absorptions for complex 4-a in acetonitrile. The dielectric continuum model (COSMO) was applied for the TD-DFT calculations.

Figure 3.17.: The absorption spectrum measured in acetonitrile and the bar-spectrum simulated based on the TD-DFT calculation for complex dpq- $\mathrm{W}^{I V} \mathrm{~W}^{I V}(4-\mathrm{a})$ in acetonitrile.

According to the TD-DFT calculations, the absorption band at 535 nm has contributions from both LMCT and MLCT transitions while the absorption at 790 nm results purely from MLCT transition. The interligand transition of $\mathrm{Cp}^{*} \rightarrow \mathrm{dpq}$ is mainly located in the near UV region.

[^9]Table 3.6 shows the COSMO molecular orbitals with major contributions to the MLCT and LMCT transitions in the range from 400 to 1000 nm . The major MLCT transitions were calculated to emerge at $814,602,486 \mathrm{~nm}$ and the LMCT transitions were expected mainly at 500, 486 nm .

Detailed data for transitions with oscillator strengths larger than 0.0058 (the oscillator strength of the HOMO $\rightarrow$ LUMO transition) for complex $4-\mathrm{a}$ is listed in Table 3.7.

Table 3.6.: Major orbital contributions of the electronic transitions in complex dpq$\mathrm{W}^{I V} \mathrm{~W}^{I V}(4-\mathrm{a})$ in the visible region calculated by TD-DFT.

| Major contributions | $\lambda(\mathrm{nm})$ | Occupied orbital | Vacant orbital |  |
| :---: | :---: | :---: | :---: | :---: |
| MLCT transitions | 814 nm |  |  | $48 \%$ $29 \%$ |
|  | 602 nm |  |  | $\begin{aligned} & 39 \% \\ & 26 \% \end{aligned}$ |
|  | 486 nm |  |  | 50\% |

${ }^{a}$ length representation of oscillator strength

The strong absorption of complex 4-a in the visible spectrum makes it a potential photosensitizer for catalytic solar water splitting. The existence of both MLCT $(\mathrm{W} \rightarrow \mathrm{dpq})$ and LMCT $\left(\mathrm{Cp}^{*} \rightarrow \mathrm{~W}\right)$ transitions will create a charge separated state $\left[C p^{*}\right]^{+}-W-[d p q]^{-}$where the positive and negative charges are separated by some distance. As reported by Wasielewski et al., ${ }^{30,31,133-135}$ the electron transfer is distance-dependent in donor-bridge-acceptor systems. This charge separation might lead to a longer lived excited state due to the slower charge recombination over a longer distance.

### 3.5.3. Raman Spectroscopy of Complex 4-a

Resonant Raman spectroscopy was employed to shed a light on the character of the electronic transitions in the visible range. The Raman spectra of complex 4a was recorded on a Bruker Raman microscope spectrometer SENTERRA using laser excitation at $532,633,785 \mathrm{~nm}$. The incident laser frequencies were chosen to be coincident with the charge transfer band energy ( 535 and 790 nm ) and a third laser excitation ( 633 nm ), where the absorption spectrum showed only weak absorptions, was employed for comparison.

Figure 3.18.: Raman spectra of complex 4-a, excitation wavelength: 532 nm (red line), 633 nm (black line).

Figure 3.18 compares the Raman spectra resonant at 532 nm with the spectra excited at 633 nm . The intensities of some of the Raman active vibrational modes are enhanced. Based on the results of DFT calculations (PBE functional, basis set: def2-TZVP), the enhanced vibrations at 1339, 1257 and $726 \mathrm{~cm}^{-1}$ are mainly vibration of the dpq ligand, while the vibrations of Cp * ligand has Raman active
bands at 1103, 1076, 1006 and $622 \mathrm{~cm}^{-1}$. This result confirms that the absorption at 535 nm of complex 4 -a (Figure 3.13) involves both $\mathrm{Cp}^{*}$ and dpq ligands, i.e. the contribution from both LMCT and MLCT transitions.

Figure 3.19 shows the Raman spectra of complex $4-\mathrm{a}$ excited at 785 and 633 nm . Due to similar absorption at 633 and 785 nm (both of them are $\mathrm{dpq} \rightarrow \mathrm{W}$ charge transfer according to TD-DFT calculations, see Figure 3.17), the Raman spectra showed great resemblance except slightly more prominent low energy molecular vibrations at 404,217 and $148 \mathrm{~cm}^{-1}$ when excited with the 785 nm NIR laser. This suggested that the same charge transfer transition is involved at both wavelengths of 633 and 785 nm , which is consistent with the assignment of the charge transfer bands at 630 and 790 nm to MLCT transitions.

Figure 3.19.: Raman spectra of complex 4-a, excitation wavelength: 785 nm (red line), 633 nm (black line).

### 3.6. Electrochemical Properties of Complex 4-a

Electrochemical experiments were carried out to study in detail the electron transfer processes of the $\mu$-oxo ditungsten(IV /IV) complex $\left[\left(\mathrm{Cp}{ }^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}$ (4-a). The cyclic voltammetry (CV) method was performed using a Bioanalytical System (BAS) 100BW potentiostat with a three-electrode configuration in a glass cell in the glove box at RT. A 0.1 M solution of $\mathrm{Bu}_{4} \mathrm{NPF}_{6}$ supporting electrolyte in either acetonitrile or THF solvent was used. Ferrocene was employed as external reference due to its well behaved electrochemical reversibility. During each CV measurement, the solution remained quiescent. $\mathrm{E}_{1 / 2}$ values for reversible processes were calculated from the middle position of cathodic and anodic redox peaks, which are used as formal redox potentials assuming that the differences in diffusion coefficients for oxidized and reduced species are negligible.

### 3.6.1. CV Measurement of $4-\mathrm{a}$ in ACN

The potential-controlled electrochemical method CV was used to study the electron transfer property of complex 4-a. The cyclic voltammogram of 4-a in ACN is shown in Figure 3.20.

Figure 3.20.: Cyclic voltammogram for complex 4-a $[1 \mathrm{mM}]$ in $\mathrm{CH}_{3} \mathrm{CN}$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ at a scan rate of $100 \mathrm{mVs}^{-1}$, GC (Glassy Carbon) electrode (diameter $=3.0 \mathrm{~mm}$ ) in 0.1 M $\mathrm{NBu}_{4} \mathrm{PF}_{6}$ acetonitrile solution.

The aforementioned DFT calculations showed that the HOMO and LUMO of complex 4-a are both centered on the tungsten metal (see Table 3.6), therefore the observed redox waves can be readily assigned to the oxidation of the metal center. The cyclic voltammogram of complex 4 -a revealed three reversible electron transfer steps at - $120 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=64 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=0.98\right)$, $-1171 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=66 \mathrm{mV}\right.$, $\left.\mathrm{I}_{p c} / \mathrm{I}_{p a}=1.09\right)$ and $-1565 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=66 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=0.99\right)$ vs. $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right] /\left[\mathrm{Cp}_{2} \mathrm{Fe}^{+}\right]$, which can be assigned to redox couples $\mathrm{W}^{V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I V}, \mathrm{~W}^{I V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I I I}$ and $\mathrm{W}^{I V} \mathrm{~W}^{I I I} / \mathrm{W}^{I I I} \mathrm{~W}^{I I I}$ respectively. The electrochemical data for complex 4-a are summarized in Table 3.8.

Table 3.8.: Results of cyclic voltammetry experiment for complex 4-a in $\mathrm{CH}_{3} \mathrm{CN}$ (vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$.

| $4-\mathbf{a}$ | $\mathrm{W}^{V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I V}$ | $\mathrm{~W}^{I V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I I I}$ | $\mathrm{~W}^{I V} \mathrm{~W}^{I I I} / \mathrm{W}^{I I I} \mathrm{~W}^{I I I}$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{E}_{1 / 2}[\mathrm{mV}]$ | -120 | -1171 | -1565 |
| $\Delta \mathrm{E}_{p}[\mathrm{mV}]$ | 64 | 66 | 66 |
| $\mathrm{I}_{p c} / \mathrm{I}_{p a}$ | 0.98 | 1.09 | 0.99 |

The difference in cathodic and anodic peak potentials $\left(\Delta \mathrm{E}_{p}\right)$ at $25^{\circ} \mathrm{C}$ is equal to $60 / n \mathrm{mV}$ for reversible multielectron transfer processes, which is derived from the relationship (eq. 3.1):

$$
\begin{equation*}
\Delta E_{p}=\frac{2.3 \cdot R \cdot T}{n \cdot F} \tag{3.1}
\end{equation*}
$$

where $n$ is the number of electron exchanged per molecule of species under study. In reality, a peak separation $\left(\Delta \mathrm{E}_{p}\right)$ of $60-70 \mathrm{mV}$ is often observed in CV experiments for reversible electron transfer due to the resistance of the solution. ${ }^{136}$ Solution resistance causes a potential drop, called IR drop, therefore distorting the Faradaic response of reversible processes. The IR drop can be minimized by optimizing the electrolyte concentration, placing the working electrode and reference electrode as close as possible and using the feedback compensation method. For reversible electron transfer, the ratio between cathodic and anodic peak current with respect to their baselines $\left(\mathrm{I}_{p c} / \mathrm{I}_{p a}\right)$ is 1 . This current ratio allows to determine that the electrogenerated species is stable on the timescale of the CV experiment. According to the values for $\Delta \mathrm{E}_{p}$ and $\mathrm{I}_{p c} / \mathrm{I}_{p a}$ of complex 4-a, the electrochemical mechanisms for the observed three redox couples can be described all as $\mathbf{E}_{r}$, which corresponds to fast one-electron transfers at the working electrode surface without geometrical reorganization in the redox steps.

## Comproportionation constant

The comproportionation constant $\mathrm{K}_{c}$ can be measured electrochemically, since eq. 3.2

$$
\begin{equation*}
\Delta G^{\circ}=-R T\left(\ln K_{c}\right)=-n F\left(\Delta E_{o x}\right) \tag{3.2}
\end{equation*}
$$

relates $\Delta \mathrm{E}_{o x}$ to the $\mathrm{K}_{c}$ of the chemical reaction (eq. 3.3)

$$
\begin{equation*}
W^{I V} W^{I V}+W^{I I I} W^{I I I} \rightleftharpoons 2 W^{I V} W^{I I I} \tag{3.3}
\end{equation*}
$$

where $\Delta \mathrm{E}_{o x}$ corresponds to the separation between the two redox potentials for the successive oxidation processes.

The comproportionation equilibrium constant in the mixed-valence species dpq$\mathrm{W}^{I V} \mathrm{~W}^{I I I}(7-\mathbf{a})$ was determined by the difference between $\mathrm{E}_{1 / 2}$ of the successive redox couples $\mathrm{W}^{I V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I I I}$ and $\mathrm{W}^{I V} \mathrm{~W}^{I I I} / \mathrm{W}^{I I I} \mathrm{~W}^{I I I}$. The derived value of $\mathrm{K}_{c}=4.6 \times 10^{6}$ is in the typical range (i.e. $10^{6} \sim 10^{12}$ ) for delocalized valence electrons in the classification of Robin and Day. ${ }^{137}$ The short distance between two tungsten metal centers ( $2.73 \AA$ ) allows the interaction by direct orbital overlap. The real electron configuration for the assigned formal oxidation state $\mathrm{W}^{I I I} \mathrm{~W}^{I V}$ is therefore $d^{2.5} d^{2.5}$ rather than $d^{3} d^{2}$.

## HOMO-LUMO energy gap

The redox potentials recorded in the cyclic voltammograms can be used to determine the LUMO and HOMO energy levels of the analyte, and the potential difference between the onset oxidation and reduction can be used to estimate the HOMO-LUMO gap. ${ }^{138}$ The energy levels for complex 4 -a was calculated from the CV data (referenced to the $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ couple) using the expressions 3.4, 3.5 and 3.6:

$$
\begin{gather*}
E_{\text {HOMO }}=-\left(4.8 \mathrm{eV}+E_{1 / 2}{ }^{o x}\right)  \tag{3.4}\\
E_{L U M O}=-\left(4.8 \mathrm{eV}+E_{1 / 2}{ }^{\text {red }}\right)  \tag{3.5}\\
E_{g}=E_{L U M O}-E_{\text {HOMO }} \tag{3.6}
\end{gather*}
$$

The HOMO and LUMO energy values of complex 4-a were estimated to be -4.68 eV and -3.63 eV vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ respectively. The derived energy gap between the HOMO and LUMO amounts to 1.05 eV .

## CV Measurement of the free dpq ligand in ACN

Based on the fact that the dpq ligand possesses a low-lying $\pi^{*}$ orbital, it is an potentially non-innocent ligand, i.e. can also be reduced itself. In order to find out, whether the redox processes observed for complex 4-a are based on the metal centers or the attached dpq ligand, further electrochemical studies were carried out for the free dpq ligand. The cyclic voltammogram for the free dpq ligand was recorded in acetonitrile (see Figure 3.21).

Figure 3.21.: Cyclic voltammogram for the free dpq ligand in $\mathrm{CH}_{3} \mathrm{CN}$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$, scan rate: $100 \mathrm{mVs}^{-1}$, GC electrode (diameter $=3.0 \mathrm{~mm}$ ), $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$.)

A reversible redox wave at $-2042 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=89 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=1.02\right)$ was observed for the free ligand dpq vs. $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right] /\left[\mathrm{Cp}_{2} \mathrm{Fe}^{+}\right]$. The formal potential of the first reduction of the dpq free ligand was used to correlate the energy of its lowest unoccupied molecular orbital, which was found to be -2.759 eV vs $\left[\mathrm{C} \mathrm{p}_{2} \mathrm{Fe}\right]^{+/ 0}$. This confirmed that the three reversible redox waves of complex 4 -a at - 120 mV , - 1171 mV and -1565 mV are based on the redox processes of the two tungsten centers.

### 3.6.2. CV Measurement of 4-a in ACN/THF Mixture

In the potential window of acetonitrile, three reversible redox waves were observed. In order to find out whether further reductive processes could take place at potentials lower than -2 V , THF was employed, which has a larger cathodic window. However, the solubility of complex $4-\mathrm{a}$ in THF is rather poor. A solvent mixture of $\mathrm{CH}_{3} \mathrm{CN} /$ THF (1:1) was used to access more negative potentials and yet retain a reasonable solubility for complex 4 -a. The cyclic voltammogram of complex 4 -a in a $\mathrm{CH}_{3} \mathrm{CN} / \mathrm{THF}(1: 1)$ solvent mixture is presented in Figure 3.22.

Figure 3.22.: Cyclic voltammogram for complex 4-a [1 mM] in $\mathrm{CH}_{3} \mathrm{CN} / \mathrm{THF}$ (1:1) vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ at a scan rate of $100 \mathrm{mVs}^{-1}$, GC electrode (diameter $=3.0 \mathrm{~mm}$ ) in 0.1 M $\mathrm{NBu}_{4} \mathrm{PF}_{6}$ solution.

The cyclic voltammogram of complex 4 -a measured in a $\mathrm{CH}_{3} \mathrm{CN} / \mathrm{THF}$ solvent mixture revealed also three tungsten based reversible redox couples at -129 mV ,1164 mV and -1560 mV , furthermore, two additional redox couples at -2116 mV $\left(\Delta \mathrm{E}_{p}=70 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=1.22\right)$ and $-2310 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=78 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=0.72\right)$. Due to the small separation between the last two redox waves, the cathodic and anodic peak currents could not be accurately determined.

## CV Measurement of the free dpq ligand in ACN/THF Mixture

The CV measurement was also performed for the free dpq ligand under the same condition in the $\mathrm{CH}_{3} \mathrm{CN} / \mathrm{THF}$ (1:1) solvent mixture. The cyclic voltammogram of the free dpq ligand (Figure 3.23) displays a reversible electron transfer at the potential of $-2087 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=75 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=1.01\right)$. Scanning the potential more negative beyond this redox process revealed no additional waves before the limit of the solvent window was reached.

Figure 3.23.: Cyclic voltammograms for dpq ligand [1 mM] in $\mathrm{CH}_{3} \mathrm{CN} / \mathrm{THF}$ (1:1) vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ at a scan rate of $100 \mathrm{mVs}^{-1}, \mathrm{GC}$ electrode (diameter $=3.0 \mathrm{~mm}$ ), 0.1 M $\mathrm{NBu}_{4} \mathrm{PF}_{6}$.

According to DFT calculations, the HOMO of dpq-W ${ }^{I I I} W^{I I I}$ is mainly based on the metal center, while the LUMO is based on the dpq ligand (see Figure 3.24). Thus, the redox waves observed at -2116 mV and -2310 mV in Figure 3.22 are assigned to the dpq ligand rather than the tungsten centers. This is also in accordance with the redox waves for the free dpq ligand located at -2087 mV (see Figure 3.23). The CV data for complex $4-\mathrm{a}$ in $\mathrm{CH}_{3} \mathrm{CN} /$ THF is summarized in Table 3.9.

By comparison with the CV measured in pure acetonitrile for $4-\mathrm{a}$, there is a notable shift of the $\mathrm{E}_{1 / 2}$ values in the THF/ACN (vol:vol 1:1) solvent mixture. The oxidation potential for $[4-\mathrm{a}]^{+} /[4-\mathrm{a}]$ is less positive in THF/ACN $(-129 \mathrm{mV})$ than in pure $\mathrm{ACN}(-120 \mathrm{mV})$ while the reduction potentials for $[4-\mathrm{a}] /[4-\mathrm{a}]^{-}$and $[4-$

a] $]^{-} /[4-\mathbf{a}]^{2-}$ are less negative in THF/ACN (- 1164 and -1560 mV ) than in pure ACN (- 1171 and -1565 mV ), indicating that complex 4 -a is more stable in ACN than in THF. This can be readily rationalized by the stronger solubility of the ionic system in the more polar ACN solvent.

### 3.7. Distinctive Electrochemical Behavior of Complex 4-b

The electrochemical behavior of complex 4-b was investigated by cyclic voltammetry in ACN, THF and a solvent mixture of ACN/THF. As will be detailed below, the electrochemical properties of the dpphen substituted $\mu$-oxo-bridged complex 4-b differ from the $\mathrm{R}_{2} \mathrm{bpy}\left(\mathrm{R}=\mathrm{NMe}_{2}, \mathrm{Me}, \mathrm{H}, \mathrm{Cl}\right)$ and dpq substituted analogues, which all showed simple $\mathrm{E}_{r}$ mechanism.

### 3.7.1. CV Measurement of 4-b in ACN

The cyclovoltammetric study was performed for complex 4-b using a platinum disk working electrode in acetonitrile. As can be seen from the black line in Figure 3.25, two reversible redox couples were observed at $-209 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=61 \mathrm{mV}\right.$, $\left.\mathrm{I}_{p c} / \mathrm{I}_{p a}=0.93\right)$ and $-1307 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=61 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=1.06\right)$ vs $\left[\mathrm{C} \mathrm{p}_{2} \mathrm{Fe}\right]^{+/ 0}$ when the cyclic voltammograme was recorded in the range of +70 to -1580 mV , which can be assigned to the $\mathrm{W}^{V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I V}$ and $\mathrm{W}^{I V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I I I}$ redox couples respectively.

However, when the range was extended to -2030 mV , a further irreversible reduction peak at -1706 mV was observed. A huge anodic Gaussian shaped current at $\mathrm{E}_{p a 2}=-1237 \mathrm{mV}\left(\mathrm{I}_{p a 2}=-9.705 \times 10^{-5} \mathrm{~A}\right)$ was detected upon sweeping back, instead of the previously observed reversible one-electron oxidation wave of $\mathrm{E}_{p a 1}$ $=-1277 \mathrm{mV}$ (see red line in Figure 3.25). The cathodic current at -1336 mV for one-electron reduction is $+1.441 \times 10^{-5} \mathrm{~A}\left(\mathrm{I}_{p c 1}\right)$, which leads to a current ration of $\mathrm{I}_{p a 2} / \mathrm{I}_{p c 1}=6.73$.

The application of platinum and glassy carbon working electrodes both led to similar voltammograms, which are reproducible and did not change in repetitive scans.

The CV of the $\mathrm{Me}_{2} \mathrm{bpy}$ substituted bis- $\mu$-oxo bridged complex $\mathrm{Me}_{2} \mathrm{bpy}-\mathrm{W}^{I V} \mathrm{~W}^{I V}$ $\left(\left[\left(\mathrm{Cp}^{*} \mathrm{~W}\left(\mathrm{Me}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}\right)$ presented in Chapter 1 Figure 1.8 revealed one reversible one-electron oxidation and two reversible one-electron reduction steps. The isolated complexes $\mathrm{Me}_{2} \mathrm{bpy}-\mathrm{W}^{V} \mathrm{~W}^{I V}$ and $\mathrm{Me}_{2} \mathrm{bpy}-\mathrm{W}^{I V} \mathrm{~W}^{I I I}$ display essentially identical geometries to complex $\mathrm{Me}_{2} \mathrm{bpy}-\mathrm{W}^{I V} \mathrm{~W}^{I V}$ with a cis orientation of the $\mathrm{Cp}{ }^{*}$ rings. On the contrary, the crystal structure analysis of the independently pre-

Figure 3.25.: Cyclic voltammograms for complex 4-b [ 0.82 mM ] in $\mathrm{CH}_{3} \mathrm{CN}$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ at a scan rate of $200 \mathrm{mVs}^{-1}, \mathrm{GC}$ electrode (diameter $=3.0 \mathrm{~mm}$ ), $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$ solution.
pared complex $\mathrm{Me}_{2} \mathrm{bpy}-\mathrm{W}^{I I I} \mathrm{~W}^{I I I}$ evidenced a trans disposition of the Cp rings. At first glance, this is conflict with the reversible wave observed for the second reduction. It was deemed that the cis-geometry of complex $\mathrm{Me}_{2} \mathrm{bpy}-\mathrm{W}^{I I I} \mathrm{~W}^{I I I}$ is maintained on the timescale of the electrochemical experiment. ${ }^{83}$ Based on those previous results, we considered an ECE mechanism for the Gaussian shape anodic wave, where the chemical steps correspond to cis/trans isomerizations.

In the case of the dpphen substituted bis- $\mu$-oxo bridged complex 4-b, the cis-trans isomerization might be faster than in the $\mathrm{Me}_{2}$ bpy substituted complex $\mathrm{Me}_{2}$ bpy$\mathrm{W}^{I V} \mathrm{~W}^{I V}$. This is supported by the higher steric repulsion for the cis-isomer in the dpphen system. In the time domain of the CV experiments, the isomerization interferes with the electrochemical behavior. The reduction mechanisms for complex 4-b can be ascribed as follows:

$$
\begin{array}{ll}
\mathbf{E}: & \text { cis }-W^{I V} W^{I V}+e \rightleftharpoons c i s-W^{I V} W^{I I I} \\
\mathbf{E}: & c i s-W^{I V} W^{I I I}+e \rightleftharpoons c i s-W^{I I I} W^{I I I} \\
\mathbf{C}: & \text { cis }-W^{I I I} W^{I I I} \rightarrow \text { trans }-W^{I I I} W^{I I I} \tag{3.9}
\end{array}
$$

$$
\begin{equation*}
\text { ECE }: \quad \text { trans }-W^{I I I} W^{I I I} \rightleftharpoons \text { cis }-W^{I V} W^{I V}+2 e \tag{3.10}
\end{equation*}
$$

The first reduction wave at -1336 mV corresponds to the one-electron reduction of cis- $W^{I V} W^{I V}$ to cis- $W^{I V} W^{I I I}$ (3.7). The second reduction wave at -1706 mV can be described as EC mechanism, which is recognized by the lack of the reverse peak. The EC process consists of an one-electron reduction at the electrode surface to form cis- $\mathrm{W}^{I I I} \mathrm{~W}^{I I I}$ and a consecutive chemical reaction in solution that converted cis-W ${ }^{I I I} W^{I I I}$ to trans- $W^{I I I} W^{I I I}$ (see 3.8 and 3.9). The shape of the last reduction wave at -1706 mV is quite sharp as compared with the other one-electron transfer peaks. This kind of peak shape typically corresponds to fast electrode kinetics and chemical kinetics. ${ }^{136}$ Furthermore, the reverse peak is virtually absent due to the fast irreversible chemical reaction following the electrode reduction. As soon as the cis- $W^{I I I} W^{I I I}$ is generated, it is removed from the electrode surface by the isomerization reaction.

With regard to the Gaussian shaped anodic wave, it is possible that the active species was adsorbed on the electrode surface, which is excluded by analysis of current dependence on scan rate (vide infra). The chemically generated species trans- $\mathrm{W}^{I I I} \mathrm{~W}^{I I I}$ has a different oxidation potential $\left(\mathrm{E}_{p}=-1237 \mathrm{mV}\right)$ as the cis-isomer. The huge anodic current $\mathrm{I}_{p a 2}$ is ascribed to a simultaneous two-electron transfer step of trans-W ${ }^{I I I} W^{I I I}$ accompanied with molecular reorganization (3.10). This process can be expressed in detail with the following equations:

$$
\begin{array}{ccc}
\mathbf{E}: & \text { trans }-W^{I I I} W^{I I I} \rightleftharpoons \text { trans }-W^{I V} W^{I I I}+e & E_{1}^{o \prime} \\
& \mathbf{C}: \quad \text { trans }-W^{I V} W^{I I I} \rightarrow \text { cis }-W^{I V} W^{I I I} & \\
\mathbf{E}: & \text { cis }-W^{I V} W^{I I I} \rightleftharpoons \text { cis }-W^{I V} W^{I V}+e & E_{2}^{o \prime} \tag{3.13}
\end{array}
$$

In principle, the addition of the first electron must render the second electron addition electrostatically unfavorable and this is the reason why most electron transfers occur sequentially. Only in the case that some molecular reorganization at the microscopic level occurs within the original molecule, which rendering available a non-bonding molecular orbital, can allow the second electron to enter simultaneously or even more favorably than the first one. ${ }^{139}$ Here, the formal electrode potential for one-electron oxidation of trans- $\mathrm{W}^{I I I} \mathrm{~W}^{I I I}, E_{1}^{o{ }^{\prime}}$, is even more positive than the formal electrode potential for one-electron oxidation of cis- $\mathrm{W}^{I V} \mathrm{~W}^{I I I} E_{2}^{o{ }^{\prime}}$. That is to say that cis- $\mathrm{W}^{I V} \mathrm{~W}^{I I I}$ is more easily oxidized than trans $-\mathrm{W}^{I I I} \mathrm{~W}^{I I I}$. Therefore the two one-electron transfers 3.11 and 3.13 take place simultaneously. The
evidence of ECE mechanism for the Gaussian shaped wave is provided by analysis of the current dependence on the scan rate (see below).

### 3.7.2. Current Dependence on Scan Rate

In order to gain further insight into the mechanism of the oxidation process of electrochemically generated neutral species [4-a ${ }^{2 \ominus}$, cyclic voltammetry of complex 4-b were analyzed at scan rates of 10, 50, 100, 200 and $500 \mathrm{mV} / \mathrm{s}$ in acetonitrile (Figure 3.26).

Figure 3.26.: Cyclic voltammograms for complex 4-b $[1.74 \mathrm{mM}]$ in $\mathrm{CH}_{3} \mathrm{CN}$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ at various scan rates, Pt electrode (diameter $=1.6 \mathrm{~mm}$ ), $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$.

The effect of the scan rate $(\nu)$ on the CV can be described by the Randle-Sevcik equation ${ }^{136}$ for an electrochemically reversible system (rapid electron transfer at the electrode surface) at $25^{\circ} \mathrm{C}$ :

$$
\begin{equation*}
I_{p}=\left(2.69 \times 10^{5}\right) \cdot n^{3 / 2} \cdot A \cdot D^{1 / 2} \cdot C \cdot \nu^{1 / 2} \tag{3.14}
\end{equation*}
$$

where

```
Ip
n is the electron stoichiometry
A is the electrode area (cm}\mp@subsup{}{}{2}
D is the diffusion coefficient (cm}\mp@subsup{}{}{2}/\textrm{s}
C is the concentration (mol/cm}\mp@subsup{}{}{3}
\nu is the scan rate (V/s)
```

Thus, $I_{p}$ is proportional to C and $\nu^{1 / 2}$ for a reversible electrode reaction. From a plot of $i_{p c}$ or $i_{p a}$ versus $\nu^{1 / 2}$ the diffusion coefficient for the system can be derived. According to the onset anodic (oxidation) current of complex 4-b presented in Figure 3.25 , the diffusion coefficient of dpphen- $W^{I V} W^{I V}$ complex in ACN solvent can be estimated as $8.0239 \times 10^{-6} \mathrm{~cm}^{2} / \mathrm{s}$ using the geometrical values for the surface of the disk electrode.

The linear dependence of the peak current for the reversible process on the square root of scan rate is most accurately determined for the initial sweep peak, which have the same initial concentration of the analyte. Figure 3.27 shows the plots of the peak current of the first oxidation and the first reduction of complex 4$\mathbf{b}$ as a function of the square root of scan rate, which clearly revealed diffusion controlled processes.

Figure 3.27.: Plots of the peak currents of the first oxidation (left) and the first reduction (right) waves of complex $4-\mathrm{b}$ in $\mathrm{CH}_{3} \mathrm{CN}$, as a function of the square root of the scan rate.

The huge anodic peak current was proportional to the square root of the scan rate at least up to $500 \mathrm{mV} / \mathrm{s}$, which clearly showed a diffusion-controlled process rather than an adsorption process (see Figure 3.28 left).

Figure 3.28.: Plots of the anodic peak current for the two-electron oxidation process of complex 4-b upon sweeping back in $\mathrm{CH}_{3} \mathrm{CN}$ as a function of the square root of scan rate (left) and as a function of scan rate (right).

The peak current $i_{p}$ involving adsorption can be given by:

$$
\begin{equation*}
i_{p}=\frac{n^{2} \cdot F^{2}}{4 \cdot R \cdot T} \cdot \nu \cdot A \cdot \Gamma_{o x} \tag{3.15}
\end{equation*}
$$

where $\Gamma_{o x}$ is the surface coverage $\left(\mathrm{mol} / \mathrm{cm}^{2}\right)$. On increasing the scan rate, the intensity of the adsorption peak should linearly increase with $\nu$, which is not this case for the Gaussian shaped current (Figure 3.28 right).

According to equation 3.1, the peak separation $\left(\Delta \mathrm{E}_{p}\right)$ is independent of the scan rate for reversible processes. However, the values for $\Delta \mathrm{E}_{p}$ derived from Figure 3.26 for the first reversible oxidation are $72,74,76$ and 90 mV for scan rates of 50 , 100,200 and $500 \mathrm{mV} / \mathrm{s}$, respectively. At higher scan rates, $\Delta \mathrm{E}_{p}$ starts to increase. This may be due to slow electron transfer kinetics or an ohmic potential (iR) drop.

When the scan rate was extended to $10 \mathrm{~V} / \mathrm{s}$, the linear dependence of the Gaussian shaped current on the square root of the scan rate ( $\nu^{1 / 2}$ ) was no longer observed (see Figure 3.29). At scan rates higher than $2 \mathrm{~V} / \mathrm{s}$, the corresponding anodic wave for the second reduction starts to appear. The current ratio $\mathrm{I}_{p r} / \mathrm{I}_{p f}$ of the second reduction increases with the scan rate up to 1 , which is the most significant evidence for a EC mechanism.

At a scan rate of $10 \mathrm{~V} / \mathrm{s}$, the chemical reaction rate is too slow to compete with the electrode reaction rate. Therefore, three reversible redox waves at - $211 \mathrm{mV}\left(\Delta \mathrm{E}_{p}\right.$ $\left.=131 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=0.94\right),-1308 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=154 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=0.91\right)$ and -1695 mV $\left(\Delta \mathrm{E}_{p}=134 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=1.18\right)$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ were observed, which can be confi-

Figure 3.29.: Cyclic voltammograms for complex 4-b [0.82 mM] in $\mathrm{CH}_{3} \mathrm{CN}$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ at various scan rates, glassy carbon electrode (diameter $=3.0 \mathrm{~mm}$ ), $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$.
dently assigned to $\mathrm{W}^{V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I V}, \mathrm{~W}^{I V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I I I}$ and $\mathrm{W}^{I V} \mathrm{~W}^{I I I} / \mathrm{W}^{I I I} \mathrm{~W}^{I I I}$ redox couples respectively. The electrochemical data for complex 4-b at a scan rate of $10 \mathrm{~V} / \mathrm{s}$ in ACN is listed in Table 3.10.

Table 3.10.: Results of cyclic voltammetry experiments for complex 4-b in ACN at a scan rate of $10 \mathrm{~V} / \mathrm{s}\left(\mathrm{vs}\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}\right)$.

| $4-\mathbf{b}$ | $\mathrm{W}^{V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I V}$ | $\mathrm{~W}^{I V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I I I}$ | $\mathrm{~W}^{I V} \mathrm{~W}^{I I I} / \mathrm{W}^{I I I} \mathrm{~W}^{I I I}$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{E}_{1 / 2}[\mathrm{mV}]$ | -211 | -1308 | -1695 |
| $\Delta \mathrm{E}_{p}[\mathrm{mV}]$ | 131 | 154 | 134 |
| $\mathrm{I}_{p c} / \mathrm{I}_{p a}$ | 0.94 | 0.91 | 1.18 |

When the scan rate is beyond $10 \mathrm{~V} / \mathrm{s}$, the $i R$ drop and charging current distortions become very significant. A cyclic voltammogram for complex 4-b at a scan rate of $15 \mathrm{~V} / \mathrm{s}$ in the full potential window of acetonitrile is provided in Figure 3.30.

Besides the previously assigned three redox waves, two additional redox waves at - $2304 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=166 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=1.22\right)$ and $-2654 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=189 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=\right.$

Figure 3.30.: Cyclic voltammograms for complex 4-b $[0.82 \mathrm{mM}]$ in $\mathrm{CH}_{3} \mathrm{CN}$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ at a scan rate of $15 \mathrm{~V} / \mathrm{s}$, glassy carbon electrode (diameter $=3.0 \mathrm{~mm}$ ), $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$.
1.26) vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ were also observed. These redox waves have potentials comparable to those of the free dpphen ligand $\left(-2359 \mathrm{mV}\right.$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ at a scan rate of $100 \mathrm{mV} / \mathrm{s}$, see Figure 3.32). It is therefore anticipated that these redox processes are also ligand based redox couples as the dpq substituted analogue 4-a. All electrochemical data for complex 4-b at a scan rate of $15 \mathrm{~V} / \mathrm{s}$ are summarized in Table 3.11.

Table 3.11.: Results of cyclic voltammetry experiments for complex 4-b in ACN at a scan rate of $15 \mathrm{~V} / \mathrm{s}\left(\mathrm{vs}\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}\right)$.

| 4-b | $\mathrm{E}_{1 / 2}[\mathrm{mV}]$ | $\Delta \mathrm{E}_{p}[\mathrm{mV}]$ | $\mathrm{I}_{p c} / \mathrm{I}_{p a}$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{~W}^{V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I V}$ | -213 | 150 | 0.92 |
| $\mathrm{~W}^{I V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I I I}$ | -1306 | 185 | 0.93 |
| $\mathrm{~W}^{I V} \mathrm{~W}^{I I I} / \mathrm{W}^{I I I} \mathrm{~W}^{I I I}$ | -1696 | 172 | 1.10 |
| dpphen ${ }^{0 /-}$ | -2304 | 166 | 1.22 |
| dpphen |  |  |  |
| 0/- | -2654 | 189 | 1.26 |

When the negative window of ACN was explored at a low scan rate of $100 \mathrm{mV} / \mathrm{s}$, decomposed complexes were observed (see Figure 3.31) instead of two ligand based reversible redox waves recorded at a scan rate of $15 \mathrm{~V} / \mathrm{s}$. From Figure 3.30 (scan rate of $15 \mathrm{~V} / \mathrm{s}$ ) and Figure 3.31 (scan rate of $100 \mathrm{mV} / \mathrm{s}$ ), we can estimate that cis- $W^{I I I} W^{I I I}$ can undergo two reversible reduction but trans- $W^{I I I} W^{I I I}$ decomposes upon reduction. This further confirmed that the consecutive two reduction waves of cis- $\mathrm{W}^{I I I} \mathrm{~W}^{I I I}$ is based on the ligand rather than the metal centers.

Figure 3.31.: Cyclic voltammograms for complex 4-b [ 0.82 mM ] in $\mathrm{CH}_{3} \mathrm{CN}$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ at a scan rate of $100 \mathrm{mV} / \mathrm{s}$, glassy carbon electrode (diameter $=3.0 \mathrm{~mm}$ ), $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$.

## CV Measurement of the Free dpphen Ligand in ACN

The electrochemical study was also performed for the free dpphen ligand under the same condition. Figure 3.32 shows a reversible redox process at -2359 mV vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ with peak separation of 77 mV near the potential window of acetonitrile solvent.

Applying eq. 3.5, the LUMO energy of the dpphen free ligand can be derived as -2.441 eV vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$, which is 0.318 eV higher than the energy of the LUMO of the free dpq ligand.

Figure 3.32.: Cyclic voltammogram for the free dpphen ligand in $\mathrm{CH}_{3} \mathrm{CN}$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ at a scan rate of $100 \mathrm{mVs}^{-1}$, Pt electrode (diameter $=1.6 \mathrm{~mm}$ ), $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$.

### 3.7.3. Solvent Dependence of Reversibility

In the course of the study, it was found that the reversibility of the electrochemical steps in the dpphen substituted $\mu$-oxo-bridged ditungsten complex 4-b is solvent dependent. This was systematically probed for different ratios of the ACN/THF mixture.

### 3.7.3.1. CV Measurement in THF

The electrochemical study of complex 4-b was also performed in THF solvent. In THF, complex 4-b is only slightly soluble and the concentration of the analyte in THF solvent is less than 1.74 mM . Normal reversible redox waves were observed in THF solvent, see Figure 3.33.

The cyclic voltammogram of complex 4-b in THF illustrates one reversible oxidation wave at $-286 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=126 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=0.97\right)$ for $\mathrm{W}^{V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I V}$, two reversible reduction waves at $-1335 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=128 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=1.18\right)$ and -1656 $\mathrm{mV}\left(\Delta \mathrm{E}_{p}=126 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=0.97\right)$ for $\mathrm{W}^{I V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I I I}$ and $\mathrm{W}^{I V} \mathrm{~W}^{I I I} / \mathrm{W}^{I I I} \mathrm{~W}^{I I I}$

Figure 3.33.: Cyclic voltammograms for complex $4-\mathbf{b}[\leq 1.74 \mathrm{mM}]$ in THF vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ at a scan rate of $100 \mathrm{mVs}^{-1}$, GC electrode $\left(\right.$ diameter $=3.0 \mathrm{~mm}$ ) in $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$ solution.
respectively. The CV data in THF for 4-b are listed in Table 3.12.

Table 3.12.: Results of cyclic voltammetry experiments for complex 4-b in THF (vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$.

| 4-b | $\mathrm{W}^{V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I V}$ | $\mathrm{~W}^{I V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I I I}$ | $\mathrm{~W}^{I V} \mathrm{~W}^{I I I} / \mathrm{W}^{I I I} \mathrm{~W}^{I I I}$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{E}_{1 / 2}[\mathrm{mV}]$ | -286 | -1335 | -1656 |
| $\Delta \mathrm{E}_{p}[\mathrm{mV}]$ | 126 | 128 | 126 |
| $\mathrm{I}_{p c} / \mathrm{I}_{p a}$ | 0.97 | 1.18 | 0.97 |

The effect of the scan rate on the voltammograms was also investigated using various scan rates: 50, 100, 200, 500 and $1000 \mathrm{mV} / \mathrm{s}$. All peak currents are linearly dependent on the square root of scan rate, which proved that all redox process are diffusion controlled.

A CV of complex 4-b at lower concentration ( $\leq 0.88 \mathrm{mM}$ ) in THF was also recorded in a wider potential range in the presence of ferrocene (Figure 3.34).

This voltammogram showed a third reversible one-electron reduction wave at $-2415 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=108 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=1.09\right)$ which is assigned to the ligand based

Figure 3.34.: Cyclic voltammograms for complex $4-\mathrm{b}$ [ $\leq 0.88 \mathrm{mM}$ ] in THF at a scan rate of $100 \mathrm{mVs}^{-1}$ in the presence of ferrocene, GC electrode (diameter $=3.0 \mathrm{~mm}$ ) in 0.1 M $\mathrm{NBu}_{4} \mathrm{PF}_{6}$ solution. Potentials are referenced to the ferrocenium/ferrocene couple shown at 0 V .
redox couple dpphen ${ }^{0 /-}$. The detailed CV data are summarized in Table 3.13. It is noted that the peak separation $\Delta \mathrm{E}_{p}$ is smaller for lower concentration of the analyte. Due to the narrow separation of the redox waves, the deviation of current ratio $\mathrm{I}_{p c} / \mathrm{I}_{p a}$ from unit is not compromising the reversibility of the process.

Table 3.13.: Results of cyclic voltammetry experiments for complex 4-b in THF (vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$.

### 3.7.3.2. CV Measurement in THF upon addition of ACN

The CV of complex 4-b ( $\leq 1.0 \mathrm{mM}$ ) in pure THF is shown in Figure 3.35 (black line). Upon addition of acetonitrile to THF, the 4 reversible redox waves shifted slightly to more negative potential without dramatic change. During the measurements of all cyclic voltammograms, the overall concentration of the electrolyte $\mathrm{NBu}_{4} \mathrm{PF}_{6}$ was kept constant at 0.1 M .

Figure 3.35.: Cyclic voltammograms for complex 4-b in THF upon addition of ACN at a scan rate of $100 \mathrm{mV} / \mathrm{s}, \mathrm{GC}$ electrode (diameter $=3.0 \mathrm{~mm}$ ) in $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$ solution.

According to equation 3.14, the current raise after addition of first 1 ml ACN is likely due to higher concentration of active species*. The CV data for complex $4-\mathrm{b}(0.5 \mathrm{mM})$ referenced to $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ in the THF/ACN (1:1) solvent mixture is provided in Table 3.14.

[^10]Table 3.14.: Results of cyclic voltammetry experiments for complex 4-b ( 0.5 mM ) in THF / $\mathrm{ACN}(1: 1)$ solvent mixture (vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ ).

### 3.7.3.3. CV Measurement in ACN upon Addition of THF

The CV of complex 4-b in ACN ( 1.0 mM ) shows an irreversible anodic diffusioncontrolled wave, which displays a substantially huger current than the other oneelectron redox waves (black line in Figure 3.36). Note that there is a baseline shift since the first scan in pure ACN was carried out with a sensitivity of $100 \mu \mathrm{~A} / \mathrm{V}$ while the residual measurements were recorded with a sensitivity of $10 \mu \mathrm{~A} / \mathrm{V}$.

Figure 3.36.: Cyclic voltammograms for complex 4-b in ACN upon addition of THF at a scan rate of $100 \mathrm{mVs}^{-1}, \mathrm{GC}$ electrode (diameter $=3.0 \mathrm{~mm}$ ) in $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$ solution.

Upon addition of THF to the ACN solution of 4-b, the anodic peak R12 decreased dramatically and disappeared (see Figure 3.36). The decrease of peak currents
against the concentration of the analyte is summarized in Figure 3.37. The peak current for the reversible process decrease linearly with the concentration, neglecting small differences of the diffusion constants. The Gaussian shaped anodic current decreases sharply and the reverse peak of the second reduction appears upon addition of THF.

Figure 3.37.: Plots of the peak currents against concentration of complex 4-b for O1c, O1a, R1c and R2c (left), for all peak currents (right).

The CV of complex 4-b ( 0.5 mM ) in ACN/THF (1:1) solvent mixture shows four reversible redox waves at $-217 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=64 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=0.94\right),-1292 \mathrm{mV}\left(\Delta \mathrm{E}_{p}\right.$ $\left.=66 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=1.11\right),-1668 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=66 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=0.95\right)$ for metal center based redox couples $\mathrm{W}^{V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I V}, \mathrm{~W}^{I V} \mathrm{~W}^{I V} / \mathrm{W}^{I V} \mathrm{~W}^{I I I}, \mathrm{~W}^{I V} \mathrm{~W}^{I I I} / \mathrm{W}^{I I I} \mathrm{~W}^{I I I}$ respectively and $-2321 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=68 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=1.09\right)$ for the ligand based redox couple dpphen ${ }^{0 /-}$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ in the potential window of solvent mixture ACN/THF (1:1). (see Table 3.15 for CV data)

Table 3.15.: Results of cyclic voltammetry experiments for complex 4-b ( 0.5 mM ) in $\mathrm{ACN} / \mathrm{THF}(1: 1)$ solvent mixture (vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ ).

| dpphen |  |  |  |
|  | -2321 | 68 | 1.09 |

The solvent dependence of the cyclic voltammetric measurements is interpretated in terms that the THF solvent is preventing the isomerization process, cis-W ${ }^{I I I} W^{I I I}$ $\rightarrow$ trans- $\mathrm{W}^{I I I} \mathrm{~W}^{I I I}$. Solvent effects on the rates of homogeneous chemical reactions are well known. In some extreme cases, ${ }^{140}$ a change of solvent can alter the reaction rate by a factor up to $c a .10^{9}$. According to transition-state theory, solvents can modify the Gibbs energy of activation by different solvation of the reactants and the activated complex. ${ }^{141}$ The mechanism for the isomerization reaction has been proposed in Figure 3.38. The transition state involves a rotation around WW bond which will rupture the W-O bond and $\pi$-bond of $\mathrm{W}-\mathrm{W}$ to give a more polar activated complex. There are different stabilization effects between THF and ACN for the reactant as well as the activated complex. The THF solvent is stabilizing both the reactant cis-W ${ }^{I I I} W^{I I I}$ and the product trans- $W^{I I I} W^{I I I}$ as they are preferentially solvated in less polar solvent THF than ACN. On the other hand, the dipolar transition state complex is preferentially solvated in the more polar solvent ACN. Therefore, it is anticipated that the activation barrier for isomerization is higher in THF than in ACN.

Figure 3.38.: One-dimensinal Gibbs energy diagram for cis-to-trans isomerization of dpq$W^{I I I} W^{I I I}$ in two different solvents ACN and THF.

Reaction rates are very sensitive to the height of the activation barrier according to Arrhenius Equation (eq. 3.16):

$$
\begin{equation*}
k=A \cdot e^{-E_{a} / R T} \tag{3.16}
\end{equation*}
$$

where $k$ is the rate constant, $A$ is the prefactor and $E_{a}$ is the activation energy. For instance, a change of only $2 \mathrm{kcal} / \mathrm{mol}$ for the activation barrier can accelerate or decelerate the reaction rate by a factor of 31 at room temperature. Accordingly, the reaction rate of isomerization is assumed to be significantly slower in THF due to its higher activation barrier. This explains the retardation of isomerization upon addition of THF solvent.

### 3.8. Photocatalysis

Based on the spectroscopic and electrochemical properties of the half-sandwich transition metal complexes of $4-\mathbf{a}$ and $4-b$, they are anticipated to have great potential as both photosensitizers and redox catalysts. Due to their absorption in the visible and NIR range at 535 and 790 nm (LMCT and MLCT transitions), the oxidizing and reducing powers of $\mathbf{4 - a}$ are enhanced from the ground state going to the excited state (see Figure 3.39).

Figure 3.39.: Proposed photo-catalysis mechanism of complex 4-a for solar water splitting.

The exited state of a photosensitizer is certainly a better electron donor and meanwhile a better electron acceptor than its ground state. According to the theoretical predictions of Rehm-Weller, ${ }^{142}$ the excited state redox potentials of a photosensitizer can be estimated based on the redox potentials of the ground state applying
corrections shown in the following equations (3.17, 3.18):

$$
\begin{align*}
& E^{o}\left(E S^{+/ 0}\right)=E^{o}\left(G S^{+/ 0}\right)-\Delta G_{E S}^{o} / F  \tag{3.17}\\
& E^{o}\left(E S^{0 /-}\right)=E^{o}\left(G S^{0 /-}\right)+\Delta G_{E S}^{o} / F \tag{3.18}
\end{align*}
$$

The exited state redox potentials of complex 4-a was estimated from the ground state redox potentials obtained by cyclic voltammetry ${ }^{28,143}$ and are presented in Figure 3.40.

Figure 3.40.: Excited and ground state redox potentials for complex 4-a (represented as $\mathrm{D}_{L}-\mathrm{M}-\mathrm{A}_{L}$, in which $\mathrm{D}_{L}$ is the donor ligand, M is the metal center, $\mathrm{A}_{L}$ is the acceptor ligand) at $25{ }^{\circ} \mathrm{C}\left(\mathrm{vs}\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}\right.$ in ACN$)$.

The excited state oxidizing potential was correlated with the optical transition energy $1.523 \mathrm{eV}(814 \mathrm{~nm})$ involving the HOMO, in which the electron transfer from metal based HOMO to acceptor ligand dpq based LUMO+4 (see Table 3.7). Meanwhile, the excited state potential for reduction was obtained by correction of the LMCT transition involve LUMO ( $2.480 \mathrm{eV}, 500 \mathrm{~nm}$ ), in which charge transfer occur from donor ligand $\mathrm{Cp}^{*}$ based HOMO-4 to metal based LUMO. The oxidation and reduction power of the excited state ( -1.643 V and 1.309 V ) are both enhanced with regard to the ground state $(-1.171 \mathrm{~V}$ and $-0.120 \mathrm{~V})$. Therefore, the excited state of the dinuclear tungsten $(I V, I V)$ half-sandwich complex [4-a] thermodynamically should be capable of water oxidation and hydrogen reduction. It should be noted however that this kind of approximation for redox potential of excited state is inaccurate, often with the uncertainties of $\pm 100 \mathrm{mV}$ or more.

Photocatalysis experiments were performed using an aqueous methanol solution of complex 4-a in a Young NMR tube under radiation with UV-light. Unfortunately no hydrogen was detected through NMR monitoring. The photocatalysis experiment was also tested in the presence of an extra electron donor N,N-Dimethylaniline, however, no hydrogen was released from the solution either. The measurements of emission spectra of complex 4 -a revealed no light
emission in the the region of $600-1200 \mathrm{~nm}$. It is likely that the emission lines are in the near infrared region, which are hard to detect. Therefore, it is unclear whether the lifetime of the excited state species is too short for water splitting. The measurements of the excited state absorption spectra will shed a light on this issue.

## 4. Molybdenum Analogues of Dinuclear $\mu$-Oxo-Bridged Half-Sandwich Complexes

To improve the redox property of the potential catalyst, the molybdenum analogues of $\mu$-oxo-bridged half-sandwich complexes $\left[\left(\mathrm{Cp}^{*} \operatorname{Mo}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}$ (8-a) and $\left[\left(\mathrm{Cp}^{*} \operatorname{Mo}\left({ }^{t} \mathrm{Bu}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(8-\mathrm{d})$ were synthesized and studied with spectroscopic and electrochemical methods.

### 4.1. Synthesis of dpq-Mo ${ }^{I V} \mathrm{Mo}^{I V}$ (8-a)

The dpq substituted dinuclear $\mathrm{Mo}^{I V} \mathrm{Mo}^{I V}$ complex 8 -a was synthesized from the monomeric complex 3-a by hydrolysis in a yield of 77\% (see Reaction Scheme 4.1). The meridional isomer of 3-a was mixed with degassed water under nitrogen. After neutralization with solid $\mathrm{NaHCO}_{3}$, the reddish purple product 8-a was precipitated by addition of $\mathrm{NH}_{4} \mathrm{PF}_{6}$, extracted with DCM and recrystallized from $\mathrm{Et}_{2} \mathrm{O} / \mathrm{CH}_{2} \mathrm{Cl}_{2}$.

Reaction Scheme 4.1: Synthesis of $\mu$-oxo-bridged molybdenum(IV,IV) half-sandwich complex $\left[\left(\mathrm{Cp}^{*} \operatorname{Mo}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(8-\mathbf{a})$.

Evidence for the structure of 8 -a is provided by the ${ }^{1} \mathrm{H}-\mathrm{NMR},{ }^{13} \mathrm{C}-\mathrm{NMR}$ and two dimensional NMR (HH-COSY, HSQC, HMBC) spectroscopy, MALDI-TOF mass spectrometry, elemental analysis and X-ray single crystal structure analysis. The ${ }^{1} \mathrm{H}$-NMR spectrum of 8 -a in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ revealed the expected 4 sets of aromatic protons of the coordinated dpq ligand at $9.12 \mathrm{ppm}(\mathrm{dd}, 4 \mathrm{H}), 8.95 \mathrm{ppm}(\mathrm{dd}, 4 \mathrm{H}), 8.86$
ppm (s, 4H), $7.96 \mathrm{ppm}(\mathrm{dd}, 4 \mathrm{H})$ and a singlet for the Cp * methyl groups at 1.51 $\operatorname{ppm}(\mathrm{s}, 15 \mathrm{H})$.

## X-ray crystal structure of 8-a

Single crystals of 8-a suitable for X-ray diffraction were obtained by slow diffusion of diethyl ether into dichloromethane solution of 8-a. The Ortep view of the solid state structure of complex 8-a is shown in Figure 4.1. Important bond lengths and angles are summarized in Table 4.1.

Figure 4.1.: Crystal structure of complex 8-a (Ortep-representation; 50\%). For reasons of clarity, hydrogen atoms and the co-crystallized solvent molecule are not shown here.

The molybdenum centers in 8-a display a square pyramidal structure similar to the tungsten analogue 4-a. The distances from the molybdenum center to the four basal coordination sites (Mo1-O1 1.978 Å, Mo1-O1_2 1.964 Å, Mo1-N1 2.208 $\AA, \mathrm{Mo} 1-\mathrm{N} 22.179 \AA$ ) are ca. $0.02 \AA$ longer than in the tungsten analogue and the averaged distance from Mo1 to the centroid of the Cp ring ( $2.036 \AA$ ) is $0.01 \AA$ longer. The Mo1-Mo1_2 bond length amounts to $2.7469 \AA$, which is roughly 0.01 $\AA$ longer than the W-W bond in 4-a. All bond angles show great resemblance with the tungsten analogue. The $\alpha$ angle formed by the two dpq ligand planes is $8.04^{\circ}$ while the torsion angle between two dpq ligands is $9.3^{\circ}$.

### 4.2. Spectral and Electrochemical Properties of Complex 8-a

### 4.2.1. Electronic Absorption Spectroscopy

The absorption spectroscopic behaviour of complex 8-a was studied for a 0.80 mM acetonitrile solution in a 0.1 cm cuvette. The Vis-NIR spectrum of complex $\mathbf{8 - a}$ is given in Figure 4.2.

In the visible and near IR range, complex 8-a exhibits two strong absorption bands at $503 \mathrm{~nm}\left(\epsilon=8287 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}\right)$ and $697 \mathrm{~nm}\left(\epsilon=3380 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}\right)$ due to MLCT and LMCT transitions. As previously stated for the tungsten analogue $4-\mathbf{a}$, the MLCT transition is due to charge transfer from the non-bonding filled $d$ orbitals of the metal center to the low-lying empty $\pi^{*}$ anti-bonding orbitals of the dpq ligand. The LMCT transition corresponds to the electron transfer from the filled bonding orbital of the Cp * ligand to an empty anti-bonding metal $d$ orbital.

Figure 4.2.: Electronic absorbance spectrum of complex 8-a in acetonitrile ( $\mathrm{C}=0.80 \mathrm{mM}$ ). Cuvette light pass length is 0.1 cm .

The orbitals of the molybdenum center are lower in energy than the tungsten analogue, thus the $d$ orbitals of molybdenum are lower in energy, hence the charge transfer bands are blue-shifted from $535 \mathrm{~nm}(2.318 \mathrm{eV}), 790 \mathrm{~nm}(1.570 \mathrm{eV})$ to 503 $\mathrm{nm}(2.465 \mathrm{eV}), 697 \mathrm{~nm}(1.780 \mathrm{eV})$ in going from tungsten to molybdenum.

### 4.2.2. Cyclic Voltammetry

The dpq substituted dinuclear $\mu$-oxo-bridged molybdenum $(I V, I V)$ half-sandwich complex 8-a was studied also electrochemically. The CV experiment was performed with the GC electrode for complex $8-\mathrm{a}$ as a 1 mM acetonitrile solution in the presence of $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$ supporting electrolyte. The cyclic voltammogram of complex 8-a at a scan rate of $100 \mathrm{mV} / \mathrm{s}$ is shown in Figure 4.3.

Five reversible redox waves were observed for complex 8-a in the potential window of acetonitrile at $166 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=62 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=0.88\right),-1201 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=\right.$ $\left.58 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=0.96\right)$ and $-1574 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=70 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=1.08\right)$, which can be safely assigned to redox couples $\mathrm{Mo}^{V} \mathrm{Mo}^{I V} / \mathrm{Mo}^{I V} \mathrm{Mo}^{I V}, \mathrm{Mo}^{I V} \mathrm{Mo}^{I V} / \mathrm{Mo}^{I V} \mathrm{Mo}^{I I I}$ and $\mathrm{Mo}^{I V} \mathrm{Mo}^{I I I} / \mathrm{Mo}^{I I I} \mathrm{Mo}^{I I I}$ respectively, followed by two dpq ligand based reduction at $-2096 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=70 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=1.10\right)$ and $-2359 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=68 \mathrm{mV}\right.$, $\left.\mathrm{I}_{p c} / \mathrm{I}_{p a}=1.01\right)$. All CV data were referenced to $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right] /\left[\mathrm{Cp}_{2} \mathrm{Fe}^{+}\right]$couple and listed in Table 4.2.

Figure 4.3.: Cyclic voltammogram for complex $8-\mathrm{a}(1 \mathrm{mM})$ in $\mathrm{CH}_{3} \mathrm{CN}$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ at a scan rate of $100 \mathrm{mVs}^{-1}$, GC electrode, $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$.

Table 4.2.: Results of cyclic voltammetry experiment for complex 8-a in $\mathrm{CH}_{3} \mathrm{CN}$.

| $8-\mathrm{a}$ | $\mathrm{E}_{1 / 2}[\mathrm{mV}]$ | $\Delta \mathrm{E}_{p}[\mathrm{mV}]$ | $\mathrm{I}_{p c} / \mathrm{I}_{p a}$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{Mo}^{V} \mathrm{Mo}^{I V} / \mathrm{Mo}^{I V} \mathrm{Mo}^{I V}$ | +166 | 62 | 0.88 |
| $\mathrm{Mo}^{I V} \mathrm{Mo}^{I V} / \mathrm{Mo}^{I V} \mathrm{Mo}^{I I I}$ | -1201 | 58 | 0.96 |
| $\mathrm{Mo}^{I V} \mathrm{Mo}^{I I I} / \mathrm{Mo}^{I I I} \mathrm{Mo}^{I I I}$ | -1574 | 70 | 1.08 |
| $\mathrm{dpq}^{0 /-}$ | -2096 | 70 | 1.10 |
| $\mathrm{dpq}^{0 /-}$ | -2359 | 68 | 1.01 |

The HOMO and LUMO energy of complex 8-a can be calculated by equations mentioned in Chapter 3 from the onset oxidation and reduction respectively. The values derived from equations 3.4, 3.5 for the HOMO and LUMO are: $\mathrm{E}_{\text {НОмо }}=-$ $4.966 \mathrm{eV}, \mathrm{E}_{L U M O}=-3.599 \mathrm{eV}$ vs. $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right] /\left[\mathrm{Cp}_{2} \mathrm{Fe}^{+}\right]$and the HOMO-LUMO energy gap $\mathrm{E}_{g}$ is 1.367 eV . The HOMO in the molybdenum complex is 0.285 eV lower than the tungsten analogue dpq- $\mathrm{W}^{I V} \mathrm{~W}^{I V}(4-\mathbf{a})$ while the LUMO energy of dpq$\mathrm{Mo}^{I V} \mathrm{Mo}^{I V}$ is 0.031 eV higher than 4 -a.

There is a tiny redox current at $\mathrm{E}_{1 / 2}=-395 \mathrm{mV}$ due to a small amount of an unknown impurity in the analyte sample of $\mathbf{8 - a}$. Although complex 8 -a was recrystallized from $\mathrm{Et}_{2} \mathrm{O} / \mathrm{DCM}$ several times, unfortunately the small amount of impurity remains in the sample.

### 4.3. Synthesis of ${ }^{t} \mathrm{Bu}_{2} \mathbf{b p y - M o}{ }^{I V} \mathbf{M o}^{I V}$ (8-d)

Complex $\left[\left(\mathrm{Cp}^{*} \mathrm{Mo}\left({ }^{t} \mathrm{Bu}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(8-\mathbf{d})$ was synthesized from mononuclear complex 3-d by hydrolysis. After neutralization with solid $\mathrm{NaHCO}_{3}$, the red product was precipitated with $\mathrm{NH}_{4} \mathrm{PF}_{6}$ (see Reaction Scheme 4.2). The analytical pure compound was obtained by extraction with DCM in a yield of $65 \%$.

Reaction Scheme 4.2: Synthesis of the $\mu$-oxo-bridged molybdenum (IV,IV) half-sandwich complex $\left[\left(\mathrm{Cp}^{*} \mathrm{Mo}\left({ }^{t} \mathrm{Bu}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(8-\mathrm{d})$.

The ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of complex 8 -d showed the expected two doublets (8.47, $7.91 \mathrm{ppm})$ and a doublet of doublet ( 7.42 ppm ) for the aromatic protons of bpy unit, a singlet at 1.29 ppm for the ${ }^{t} \mathrm{bu}$ substituents and a singlet at 1.37 ppm for Cp * ligand. All signals showed high field shifts compared to the mononuclear complex 3-d. ${ }^{13} \mathrm{C}-\mathrm{NMR}$ and 2D-NMR techniques (HH-COSY, HSQC, HMBC) were employed to assign the observed signals. Further evidence for the structure of complex 8-d was provided by mass spectrometry, elemental analysis and X-ray crystallography.

## X-ray crystal structure of 8-d

Single crystals of 8-d suitable for X-ray crystal structure analysis were grown by diffusion of diethyl ether into a dichloromethane solution. The Ortep representation of the dication 8-d is shown in Figure 4.4 and relevant bond lengths and angles are presented in Table 4.3.

The two molybdenum $(I V)$ centers both adopt a square pyramidal geometry employing five coordination sites and are bridged by two oxygen atoms. The axial

Figure 4.4.: Crystal structure of complex 8-d (Ortep-representation; 50\%). For reasons of clarity, hydrogen atoms and the co-crystallized solvent molecule are not shown.
distances of Mo1-Z1 and MO2-Z2 amount to 2.035 and $2.038 \AA$ respectively.* The basal Mo-O distances in 8-d $(1.9325 \sim 1.9401 \AA)$ are significantly shorter than the Mo-O distance in the dpq substituted complex 8-a (1.964~1.978 $\AA$ ). The distance between the two metal centers $(2.7187 \AA$ ) is $0.0282 \AA$ shorter than the Mo1-Mo2 distance in the dpq substituted complex 8-a. The bite angles of N1-Mo-N2 (73.26 $\AA$ ) and N3-Mo2-N4 (73.19 A) are also smaller than in 8 -a. The bulky ${ }^{t}$ bu substituents of the bpy ligand in complex 8 -d apparently cause a dramatic increase of the $\alpha$ angle formed by two bipyridine planes to $38.72^{\circ}$, while the torsion angle $\beta$ between two ${ }^{t} \mathrm{Bu}_{2}$ bpy ligands is just $3.0^{\circ}$, which is comparable to the angles in the ${ }^{t} \mathrm{Bu}_{2}$ bpy substituted tungsten analogue $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}\left({ }^{t} \mathrm{Bu}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2} .{ }^{83}$

### 4.4. Spectral and Electrochemical Properties of Complex 8-d

### 4.4.1. Electronic Absorption Spectroscopy

The electronic absorption spectrum was recorded for a $0.71 \mathrm{mM} 8-\mathrm{d}$ solution in acetonitrile in the visible and near IR region. (see Figure 4.5)

Figure 4.5.: Electronic absorbance spectrum of complex 8 -d in acetonitrile $(C=0.71 \mathrm{mM})$.

In the absorption spectrum of complex 8-d, one charge transfer bands at 535 nm with extinction coefficient $11490 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}$ and two weaker bands at $687 \mathrm{~nm}(\epsilon=$ $\left.2698 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}\right)$, $851 \mathrm{~nm}\left(\epsilon=1783 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}\right)$ were observed.

### 4.4.2. Cyclic Voltammetry

Cyclic voltammetry was applied for complex 8-d to investigate the electron transfer mechanisms in acetonitrile and THF. The cyclic voltammograms of the ${ }^{t} \mathrm{Bu}_{2}$ bpy substituted molybdenum $(I V, I V)$ complex $8-\mathrm{d}$ in ACN at a scan rate of $100 \mathrm{mVs}^{-1}$ (Figure 4.6) are comparable with the dpphen substituted tungsten(IV,IV) halfsandwich complex $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\text { dpphen })(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(4-\mathrm{b})$.

When the CV was acquired before the second reduction wave was reached, two reversible redox waves were observed at +3 and -1566 mV for the redox couples $\mathrm{Mo}^{V} \mathrm{Mo}^{I V} / \mathrm{Mo}^{I V} \mathrm{Mo}^{I V}\left(\Delta \mathrm{E}_{p}=63 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=0.98\right)$ and $\mathrm{Mo}^{I V} \mathrm{Mo}^{I V} / \mathrm{Mo}^{I V} \mathrm{Mo}^{I I I}$ $\left(\Delta \mathrm{E}_{p}=59 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=1.15\right)$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$, respectively (see black line in Figure 4.6). The second reduction process is consistent with a EC mechanism, which is a rapid irreversible chemical reaction following the electron transfer. The corresponding anodic peak of the second reduction process is absent because all the reduced form produced near the electrode is instantly removed by fast chemical reaction. Based on the previous results for the dpphen substituted tungsten system, a fast cis-trans isomerization process is anticipated. The huge anodic current observed at -1566 mV vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$, which is 5.7 times as the one-electron ca-

Figure 4.6.: Cyclic voltammograms for complex $8-\mathbf{d}(0.88 \mathrm{mM})$ in $\mathrm{CH}_{3} \mathrm{CN}$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ at a scan rate of $100 \mathrm{mVs}^{-1}$, GC electrode, $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$.
thodic current, is caused by simultaneous two-electron transfer accompanied by trans-cis isomerization, which can be described as ECE mechanism (see red line in Figure 4.6).

The HOMO and LUMO energy of complex 8-d were calculated as -4.803 eV and -3.234 eV vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ respectively, which gave a HOMO-LUMO energy gap $\left(\mathrm{E}_{g}\right)$ of 1.569 eV . The HOMO-LUMO energy gap for the ${ }^{t} \mathrm{Bu}_{2}$ bpy substituted dimolybednum $(I V / I V)$ complex $8-\mathbf{d}$ is thus 0.202 eV bigger than the dpq substituted analogue 8-a.

## Influence of scan rate

The reversible two redox processes of complex 8-d in acetonitrile observed in the range of +440 to -1840 mV were studied at various scan rates from 20 to 2000 $\mathrm{mV} / \mathrm{s}$ (see Figure 4.7).

Figure 4.7.: Cyclic voltammograms for complex $8-\mathrm{d}(0.88 \mathrm{mM})$ in $\mathrm{CH}_{3} \mathrm{CN}$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ at scan rates from 20 to $2000 \mathrm{mVs}^{-1}$, GC electrode, $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$.

Figure 4.8.: Plots of the peak current for the first oxidation (left) and the first reduction (right) of complex $8-\mathrm{d}$ in $\mathrm{CH}_{3} \mathrm{CN}$, as a function of the square root of scan rate.

Figure 4.8 shows that the anodic current of one-electron oxidation and the cathodic current of one-electron reduction are increasing linearly with the square root of the scan rate, which means these peaks are diffusion controlled processes.

Scan rate variations on the full potential window of acetonitrile were also investigated from 0.02 to $10 \mathrm{~V} / \mathrm{s}$ for complex 8-d. Figure 4.9 shows the currents for
scan rates in the range of 20 to $100 \mathrm{mV} / \mathrm{s}$, in which the huge anodic peak is still diffusion controlled owing to the current increase as a function of the square root of the scan rate.

Figure 4.9:: Cyclic voltammograms for complex $8-\mathrm{d}(0.88 \mathrm{mM})$ in $\mathrm{CH}_{3} \mathrm{CN}$ at scan rates from 20 to $100 \mathrm{mVs}^{-1}$, GC electrode, $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$.

Cyclic voltammograms of complex 8-d at scan rates from 0.3 to $10 \mathrm{~V} / \mathrm{s}$ are presented in Figure 4.10. When the scan rate reached $1 \mathrm{~V} / \mathrm{s}$, the corresponding anodic peak of the second reduction started to show up. As the scan rate is further increasing, the Gaussian shaped current was decreasing, while the anodic current of second reduction was increasing. Three reversible redox waves were observed at a scan rate of $8 \mathrm{~V} / \mathrm{s}$ at $+3 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=125 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=0.91\right)$, - 1573 $\mathrm{mV}\left(\Delta \mathrm{E}_{p}=141 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=1.02\right)$ and $-1942 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=128 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=1.04\right)$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ which can be assigned tp redox couples $\mathrm{Mo}^{V} \mathrm{Mo}^{I V} / \mathrm{Mo}^{I V} \mathrm{Mo}^{I V}$, $\mathrm{Mo}^{I V} \mathrm{Mo}^{I V} / \mathrm{Mo}^{I V} \mathrm{Mo}^{I I I}$ and $\mathrm{Mo}^{I V} \mathrm{Mo}^{I I I} / \mathrm{Mo}^{I I I} \mathrm{Mo}^{I I I}$ respectively. The electrochemical data for complex 8-d at a scan rate of $8 \mathrm{~V} / \mathrm{s}$ are listed in Table 4.4.

Figure 4.10.: Cyclic voltammograms for complex 8-d ( 0.88 mM ) in $\mathrm{CH}_{3} \mathrm{CN}$ at scan rates from 0.3 to $10 \mathrm{Vs}^{-1}$, GC electrode, $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$.

Table 4.4.: Results of cyclic voltammetry experiment for complex 8-d in ACN at a scan rate of $8 \mathrm{~V} / \mathrm{s}$.

| $8-\mathbf{8}$ | $\mathrm{E}_{1 / 2}[\mathrm{mV}]$ | $\Delta \mathrm{E}_{p}[\mathrm{mV}]$ | $\mathrm{I}_{p c} / \mathrm{I}_{p a}$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{Mo}^{V} \mathrm{Mo}^{I V} / \mathrm{Mo}^{I V} \mathrm{Mo}^{I V}$ | +3 | 125 | 0.91 |
| $\mathrm{Mo}^{I V} \mathrm{Mo}^{I V} / \mathrm{Mo}^{I V} \mathrm{Mo}^{I I I}$ | -1573 | 141 | 1.02 |
| $\mathrm{Mo}^{I V} \mathrm{Mo}^{I I I} / \mathrm{Mo}^{I I I} \mathrm{Mo}^{I I I}$ | -1942 | 128 | 1.04 |

As can be seen from the CV data above, the capacitive current and IR drop becomes significant at high scan rates. With regard to the chemical reaction (isomerization) rate involved in the electrochemical measurements for complex 8-d and the dpphen substituted tungsten analogue $4-\mathbf{b}$, the cis-trans isomerization for 8-d is slower than in 4-b as the anodic current for the cis-isomer is present for complex $8-\mathrm{d}$ but absent for complex $4-\mathrm{b}$ at a scan rate of $2 \mathrm{~V} / \mathrm{s}$.

## Solvent dependence of reversibility

The solvent dependence of the electrochemical behavior for complex 8-d was probed by addition of a $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$ THF solution to the ACN solution of the analyte 8 -d at a scan rate of $100 \mathrm{mV} / \mathrm{s}$ (see Figure 4.11). The overall concentration of the $\mathrm{NBu}_{4} \mathrm{PF}_{6}$ electrolyte was kept at 0.1 M for all CV measurements.

Figure 4.11.: Cyclic voltammograms for complex 8-d in ACN upon addition of THF at a scan rate of $100 \mathrm{mVs}^{-1}$, GC electrode, $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$.

Upon addition of THF, the Gaussian shaped anodic current decreased dramatically; the oxidation wave for the second reduction made appearance. Finally three reversible redox waves were observed for a $1: 1$ solvent mixture of ACN/THF at a scan rate of $100 \mathrm{mVs}^{-1}$ (Figure 4.12).

The reversible redox processes observed at $-7 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=68 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=0.96\right)$, $-1545 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=64 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=1.10\right)$ and $-1915 \mathrm{mV}\left(\Delta \mathrm{E}_{p}=64 \mathrm{mV}, \mathrm{I}_{p c} / \mathrm{I}_{p a}=0.95\right)$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ can be safely assigned to redox couples $\mathrm{Mo}^{V} \mathrm{Mo}^{I V} / \mathrm{Mo}^{I V} \mathrm{Mo}^{I V}$, $\mathrm{Mo}^{I V} \mathrm{Mo}^{I V} / \mathrm{Mo}^{I V} \mathrm{Mo}^{I I I}$ and $\mathrm{Mo}^{I V} \mathrm{Mo}^{I I I} / \mathrm{Mo}^{I I I} \mathrm{Mo}^{I I I}$ respectively. The electrochemical data of complex 8-d in ACN/THF(1:1) are listed in Table 4.5.

Figure 4.12.: Cyclic voltammograms for complex 8 -d ( 0.5 mM ) in $\mathrm{ACN} / \mathrm{THF}(1: 1)$ vs $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ at a scan rate of $100 \mathrm{mVs}^{-1}$, GC electrode, $0.1 \mathrm{M} \mathrm{NBu}_{4} \mathrm{PF}_{6}$.

Table 4.5.: Results of the cyclic voltammetry experiment for complex 8-d in ACN/THF(1:1).

| $8-\mathbf{d}$ | $\mathrm{E}_{1 / 2}[\mathrm{mV}]$ | $\Delta \mathrm{E}_{p}[\mathrm{mV}]$ | $\mathrm{I}_{p c} / \mathrm{I}_{p a}$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{Mo}^{V} \mathrm{Mo}^{I V} / \mathrm{Mo}^{I V} \mathrm{Mo}^{I V}$ | -7 | 68 | 0.96 |
| $\mathrm{Mo}^{I V} \mathrm{Mo}^{I V} / \mathrm{Mo}^{I V} \mathrm{Mo}^{I I I}$ | -1545 | 64 | 1.10 |
| $\mathrm{Mo}^{I V} \mathrm{Mo}^{I I I} / \mathrm{Mo}^{I I I} \mathrm{Mo}^{I I I}$ | -1915 | 64 | 0.95 |

The ${ }^{t} \mathrm{Bu}_{2}$ bpy free ligand was also investigated electrochemically by cyclic voltammetry method. However in the cathodic potential window of acetonitrile, it is not redox active.

The electrochemical properties of the dpq and ${ }^{t} \mathrm{Bu}_{2} \mathrm{bpy}$ substituted dimolybdenum half-sandwich complexes were compared with the dpq, dpphen and $R_{2} b p y$ $\left(\mathrm{R}=\mathrm{NMe}_{2}, \mathrm{Me}, \mathrm{H} \text { and } \mathrm{Cl}\right)^{83}$ substituted ditungsten analogues in Table 4.6. As Cremer demonstrated, the linear correlation of the Hammett parameters for the substituents R and the measured potentials showed that the more electron donating R substituents led to more negative potentials. The dpq substituted ditungsten $(I V, I V)$ complex has the comparable HOMO and LUMO energy as complex $\mathrm{Cl}_{2}$ bpy- $\mathrm{W}^{I V} \mathrm{~W}^{I V}$. The oxidation potential for dpq substituted dinuclear complex increases in going from tungsten to molybdenum by roughly 0.29 V while the reduction potentials remains similar.
Table 4.6.: Summary of electrochemical data for the $\mu$-oxo-bridged ditungsten and dimolybdenum complexes $\left(\mathrm{vs}\left[\mathrm{Cp}{ }_{2} \mathrm{Fe}\right]^{+/ 0}\right)$.

## 5. Summary

The development of synthetic molecular water splitting catalysts is an urgent task facing the world's energy supply. Among many approaches, the dinuclear tungsten systems described herein are also potential photocatalysts towards solar water splitting. The chemistry of half-sandwich complexes of tungsten in medium oxidation states was previously established by Cremer. ${ }^{82-84}$ In this research work, several efforts were made to synthesize and characterize dinuclear group 6 transition metal complexes with improved photochemical and electrochemical properties.

First of all, several novel mononuclear and dinuclear group 6 organometallic complexes were synthesized and fully characterized. This includes mononuclear dipyrido[3,2-f:2', $\left.3^{\prime}-h\right]$ quinoxoline (dpq) substituted half-sandwich tungsten(IV) and molybdenum(IV) complex (2-a and 3-a), 4,7-diphenyl-1,10-phenanthroline (dpphen) substituted tungsten analogue (2-b), the 4,4'-di-tert-butyl-2,2'-dipyridyl $\left({ }^{t} \mathrm{Bu}_{2}\right.$ bpy) substituted molybdenum analogue (3-d) as well as further dinuclear oxo-bridged tungsten and molybdenum compounds $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}$ (4-a), $\left[\left(\mathrm{Cp}^{*} \operatorname{Mo}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(8-\mathbf{a}), \quad\left[\left(\mathrm{Cp}{ }^{*} \mathrm{~W}(\text { dpphen })(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(4-\mathbf{b})$ and $\left[\left(\mathrm{Cp}^{*} \mathrm{Mo}\left({ }^{t} \mathrm{Bu}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(8-\mathrm{d})$.

Strong absorption arising from MLCT and LMCT transition were observed in the UV/vis and NIR region for all ditungsten and dimolybdenum compound described here. The extinction coefficients are in the order of $10^{4} \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}$. Among them, complex 4-b absorbs the strongest and has a molar extinction coefficient of $17469 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}$ at wavelength of 590 nm . The molybdenum complexes absorb weaker and at lower wavelengths compared to the tungsten complexes. TD-DFT calculations were carried out to interpret the observed absorption bands for the $\mu$-oxo-bridged ditungsten(IV,IV) complex 4-a. According to the TD-DFT calculations, the absorption band at 535 nm has contributions from both LMCT and MLCT transitions while the absorption at 790 nm results purely from MLCT transition. The interligand transition of $\mathrm{Cp}^{*} \rightarrow \mathrm{dpq}$ is mainly located in the near UV region. Here, LMCT attributes to charge transfer from the $\mathrm{Cp}^{*} \pi$ donor ligand to the $\mathrm{W}^{I V}$ metal centers, while MLCT bands correspond to the electron transfer from the metal based orbital to the empty low lying $\pi^{*}$ orbital of the dpq ligand. Further evidence for the bands assignments was provided by resonant Raman spectroscopy. When the incident laser frequency was chosen to be coincident
with the charge transfer band at 535 nm , the intensities of some of the Raman active vibrational modes are enhanced. Based on the results of DFT calculations (PBE functional), the enhanced vibrations incorporate vibrations of the dpq ligand and the $\mathrm{Cp}{ }^{*}$ ligand. This result confirms that the absorption at 535 nm of complex 4-a involves both $\mathrm{Cp}^{*}$ and dpq ligands, i.e. the contribution of both LMCT and MLCT transitions.

The potential-controlled electrochemical method CV was used to study the electron transfer properties of these dinuclear tungsten and molybdenum complexes. The dpq substituted ditungsten and dimolybdenum complexes exhibit both three reversible metal based redox processes as well as two reversible ligand based reductions. The oxidation potential for the dpq substituted dinuclear complexes increases in going from tungsten to molybdenum by roughly 0.29 V while the reduction potentials remain similar. With regard to complex dpphen- $\mathrm{W}^{I V} \mathrm{~W}^{I V}$ (4-b) and complex ${ }^{t} \mathrm{Bu}_{2} \mathrm{bpy}-\mathrm{Mo}^{I V} \mathrm{Mo}^{I V}$ (8-d), irreversible redox behaviour were observed at lower scan rate (from $10 \mathrm{mV} / \mathrm{s}$ up to $6 \mathrm{~V} / \mathrm{s}$ ) and the Gaussian shaped anodic current attribute to simultaneous two-electron transfer step coupled with trans-cis isomerization. In oxidation state of $\mathrm{M}^{I I I} \mathrm{M}^{I I I}(\mathrm{M}=\mathrm{W}, \mathrm{Mo})$, complex dpphen- $W^{I I I} W^{I I I}$ and complex ${ }^{t} \mathrm{Bu}_{2} \mathrm{bpy}-\mathrm{Mo}^{I I I} \mathrm{Mo}^{I I I}$ favor trans orientation of the Cp* ligands in acetonitrile ( ACN ) due to steric repulsion between the bulky phenyl and ${ }^{t}$ Bu substituents. At very high scan rate ( $15 \mathrm{~V} / \mathrm{s}$ for dpphen-WW and $8 \mathrm{~V} / \mathrm{s}$ for ${ }^{t} \mathrm{Bu}_{2} \mathrm{bpy}-\mathrm{MoMo}$ ), the electrode reaction becomes much faster than the chemical reaction therefore reversible redox waves were observed. In addition, solvent dependence was also noticed for the electrochemical reversibility of complexes $\mathbf{4 - b}$ and $8-\mathbf{d}$. THF solvent is preventing the cis-trans isomerization process of neutral complex $\mathrm{M}^{I I I} \mathrm{M}^{I I I}$, in other words, the cis-trans isomerization is much faster in ACN than in THF. According to transition-state theory, solvents can modify the Gibbs energy of activation by different solvation of the reactants and the activated complex. The transition state of isomerization involves a rotation around $\mathrm{W}-\mathrm{W}$ bond which will rupture the $\mathrm{W}-\mathrm{O}$ bond and $\pi$-bond of $\mathrm{W}-\mathrm{W}$ to give a more polar activated complex. This polar transition state compound is preferentially solvated in the more polar solvent ACN. Therefore, it is anticipated that the activation barrier for isomerization is lower in ACN than in THF. Accordingly, the reaction rate of isomerization is assumed to be significantly slower in THF due to its higher activation barrier. This explains the retardation of isomerization upon addition of THF solvent. The dpphen ligand based redox waves were also observed for the dpphen substituted ditungsten complex in ACN, while the pure
${ }^{t} \mathrm{Bu}_{2}$ bpy ligand based redox waves are not present in the potential window of the utilized electrochemical solvent ACN.

The dinuclear tungsten and molybdenum (IV/IV) $\mu$-oxo-bridged complexes offer several advantages as homogeneous photocatalysts:

1. Strong light absorption with high molecular absorption coefficients ( $\epsilon$ up to $1.75 \times 10^{4} \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}$ ) were observed due to the presence of MLCT and LMCT transition in the visible and NIR region.
2. They are highly redox-active. These complexes can undergo 3 to 5 reversible one-electron transfer making the application of the complexes as a multi-electron catalyst possible.
3. These complexes can combine the role of an photosensitizer and a redox catalyst. The redox power is enhanced from the ground state to the excited state under radiation, which is thermodynamically capable of water oxidation and hydrogen reduction.

The photocatalysis experiments showed no evidence for hydrogen production or oxygen evolution under radiation yet. The measurements of emission spectra of complex 4-a revealed no light emission in the region of 600-1200 nm. It is likely that the emission lines are in the near infrared region, which are hard to detect. Therefore, it is unclear whether the lifetime of the excited state species is too short for water splitting. The measurements of the excited state absorption spectra will shed a light on this issue.

## Zusammenfassung

Die Entwicklung von Katalysatoren zur molekularen Wasserspaltung ist eine wichtige Aufgabe im Hinblick auf die weltweite Energieversorgung. Neben vielen anderen Ansätzen ist das hier beschriebene dinukleare Wolfram-System ein potentieller Katalysator zur photochemischen Wasserspaltung. Die Chemie von Wolfram-Halbsandwich-Komplexen in mittleren Oxidationsstufen wurde bereits von Cremer beschrieben. Im Zuge dieser Arbeit wurden zahlreiche Versuche unternommen, dinukleare Übergangsmetallkomplexe der Gruppe 6 mit verbesserten photo- und elektrochemischen Eigenschaften zu synthetisieren und charakterisieren.

Zunächst wurden zahlreiche neue mono- und dinukleare Organometallkomplexe der Gruppe 6 synthetisiert und vollständig charakterisiert, darunter dipyrido[3,2$\left.f: 2^{\prime}, 3^{\prime}-h\right] q u i n o x o l i n(d p q)$-substituierte Halbsandwich Wolfram(IV)- und Molyb-dän(IV)-Komplexe (2-a und 3-a), das 4,7-diphenyl-1,10-phenanthrolin (dpphen)substituierte Wolfram-Analogon (2-b), das 4,4'-di-tert-butyl-2,2'-dipyridyl ( ${ }^{[ } \mathrm{Bu}_{2}{ }^{-}$ bpy)-substituierte Molybdän-Analogon (3-d) sowie weitere dinukleare, sauerstoffverbrückte Wolfram- und Molybdän-Verbindungen $\left[\left(C p^{*} W(d p q)(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}$ (4-a), $\left[\left(\mathrm{Cp}^{*} \operatorname{Mo}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(8-\mathbf{a}),\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpphen})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}$ (4-b) und $\left[\left(\mathrm{Cp}^{*} \mathrm{Mo}\left({ }^{t} \mathrm{Bu}_{2} \mathrm{bpy}\right)(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(8-\mathrm{d})$.

Starke Absorption infolge von MLCT- und LMCT-Übergängen wurden im UV/vis- und NIR-Bereich für alle hier beschriebenen Di-Wolfram- und Di-Molyb-dän-Verbindungen beobachtet. Die Extinktionskoeffizienten liegen in der Größenordnung von $10^{4} \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}$. Die stärkste Absorption zeigt Komplex 4-b, der einen molaren Extinktionskoeffizienten von $17469 \mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}$ bei einer Wellenlänge von 590 nm aufweist. Die Molybdän-Komplexe zeigen im Vergleich zu den Wolfram-Komplexen schwächere Absorptionen bei kleineren Wellenlängen. Zur Interpretation der beobachteten Absorptionsbanden des $\mu$-Oxo-verbrückten Di-Wolfram-(IV,IV)-Komplexes 4-a wurden TD-DFT-Rechnungen herangezogen. Denen zufolge tragen sowohl die LMCT- als auch die MLCT-Übergänge zu der Absorptionsbande bei 535 nm bei, während die Absorption bei 790 nm lediglich aus MLCT-Übergängen resultiert. Der Ligand-Ligand-Übergang von $\mathrm{Cp}{ }^{*} \rightarrow \mathrm{dpq}$ ist hauptsächlich in der nahen UV-Region zu beobachten. Hierbei ist der LMCTÜbergang dem Ladungstransfer vom $\mathrm{Cp}^{*}$ - $\pi$-Donor-Liganden zum Wolfram(IV)Metallzentrum zuzuordnen, während die MLCT-Banden dem Elektronenüber-
gang von den Orbitalen des Metalls zu den leeren, energetisch niedriger liegenden $\pi^{*}$-Orbitalen des dpq-Liganden entsprechen. Weitere Bestätigung für die Bandenzuordnung liefert die Resonanz-Raman-Spektroskopie. Wenn die Einstrahlfrequenz entsprechend der Frequenz der Charge-Transfer-Bande bei 535 nm gewählt wurde, wurden die Intensitäten einiger Raman-aktiver Schwingungsmoden verstärkt. Ausgehend von den Ergebnissen der DFT-Rechnungen (PBE-Funktional) beinhalten die verstärkten Schwingungen Beiträge von Schwingungen des dpq- und des Cp*-Liganden. Dieses Ergebnis bestätigt, dass an der Absorption des Komplexes 4 -a bei 535 nm sowohl der $\mathrm{Cp}^{*}$ - als auch der dpq-Ligand beteiligt sind, folglich also sowohl LMCT- als auch MLCT-Übergänge.

Die potentialkontrollierte elektrochemische Methode CV wurde zur Untersuchung der Elektronenübertragungseigenschaften der dinuklearen Wolfram- und Molybdän-Komplexe verwendet. Die dpq-substituierten Di-Molybdän und Wolfram-Komplexe zeigen jeweils drei reversible, metallbasierte Redox-Vorgänge, ebenso wie zwei ligandenbasierte Reduktionen. Das Oxidationspotential für die dpq-substituierten dinuklearen Komplexe nimmt von Wolfram zu Molybdän um etwa 0.29 V zu , während die Reduktionspotentiale gleichbleiben. Im Falle der Komplexe dpphen- $W^{I V} W^{I V}$ (4-b) und ${ }^{t} \mathrm{Bu}_{2} b p y-\mathrm{Mo}^{I V} \mathrm{Mo}^{I V}$ (8-d) wurde ein irreversibles Redoxverhalten bei niedriger Scanrate (von $10 \mathrm{mV} / \mathrm{s}$ bis $6 \mathrm{~V} / \mathrm{s}$ ) beobachtet. Der Gauss-förmige Anodenstrom lässt auf einen simultanen ZweiElektronentransfer gekoppelt mit einer trans-cis-Isomerisierung schließen. In den Oxidationsstufen $\mathrm{M}^{I I I} \mathrm{M}^{I I I}(\mathrm{M}=\mathrm{Mo}, \mathrm{W})$ bevorzugen die Komplexe dpphen$\mathrm{W}^{I I I} \mathrm{~W}^{I I I}$ und ${ }^{t} \mathrm{Bu}_{2}$ bpy- $\mathrm{Mo}^{\text {III }} \mathrm{Mo}^{\text {III }}$ in Acetonitril (ACN) aufgrund sterischer Abstoßung der raumgreifenden Phenyl- und ${ }^{t}$ Bu-Substituenten trans-Orientierung der $\mathrm{Cp}^{*}$-Liganden. Bei hohen Scanraten ( $15 \mathrm{~V} / \mathrm{s}$ für dpphen-WW und $8 \mathrm{~V} / \mathrm{s}$ für ${ }^{t} \mathrm{Bu}_{2}$ bpy-MoMo) wird die Reaktion an der Elektrode signifikant schneller als die chemische Reaktion, so dass reversible Redoxwellen beobachtet werden. Darüber hinaus wurde für die elektrochemische Reversibilität der Komplexe 4-b und 8-d eine Lösungsmittelabhängigkeit festgestellt. THF als Lösungsmittel verhindert den cis-trans-Isomerisierungsvorgang neutraler Komplexe des Typs $\mathrm{M}^{I I I} \mathrm{M}^{I I I}$. Das bedeutet, dass die cis-trans-Isomerisierung in ACN erheblich schneller abläuft als in THF. Der Theorie des Übergangszustands (TST) zufolge sind Lösungsmittel in der Lage die Aktivierungsenergie durch verschiedenartige Solvatisierung der Reaktanden und des aktivierten Komplexes zu beeinflussen. Der Übergangszustand der Isomerisierung beinhaltet eine Rotation um die W-WBindung, die einen Bindungsbruch der W-O-Bindung und W-W- $\pi$-Bindung zur

Folge hat, wodurch ein stärker polarer aktivierter Komplex gebildet wird. Dieser Komplex wird in dem stärker polaren Lösungsmittel ACN bevorzugt gelöst. Daher wird angenommen, dass die Aktivierungsbarriere der Isomerisierung in ACN niedriger ist als in THF. Daraus lässt sich schließen, dass die Reaktionsgeschwindigkeit der Isomerisierung aufgrund der höheren Aktivierungsbarriere in THF kleiner ist. Dies erklärt die Verzögerung der Isomerisierung bei Zugabe von THF. Die auf dem dpphen-Liganden basierenden Redoxwellen wurden ebenfalls für den dpphen-substituierten Wolfram-Komplex in ACN beobachtet, wogegen die auf reinen ${ }^{t} \mathrm{Bu}_{2}$ bpy-Liganden basierenden Redoxwellen im Potentialfenster des verwendeten elektrochemischen Lösungsmittel ACN nicht auftreten.

Dinukleare $\mu$-Oxo-verbrückte Wolfram- und Molybdän- Komplexe (IV/IV) bieten diverse Vorteile als homogene Photokatalysatoren:

1. Aufgrund der MLCT- und LMCT-Übergänge wurden starke Lichtabsorptionen mit hohen molekularen Absorptionskoeffizienten (mit $\epsilon$ bis zu $1.75 \times 10^{4}$ $\mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}$ ) im sichtbaren und NIR-Bereich beobachtet.
2. Diese Verbindungen sind hoch redoxaktiv, können drei bis fünf reversible Ein-Elektronentransfers durchlaufen und eignen sich somit als MultielektronenKatalysatoren.
3. Jene Verbindungen können die Funktionen eines Photosensibilisators und Redox-Katalysators kombinieren. Die Redoxaktivität wird durch Promotion der Elektronen vom Grundzustand in den angeregten Zustand mittels Strahlung erhöht, wodurch Wasser-Oxidation und Wasserstoff-Reduktion thermodynamisch möglich werden.

Bis jetzt zeigten die photokatalytischen Experimente keine Beweise für die strahlungsinduzierte Entstehung von Wasserstoff oder Sauerstoff-Freisetzung. Die gemessenen Emissionsspektren von Komplex 4-a zeigten keine Lichtemission im Bereich von 600 bis 1200 nm . Wahrscheinlich liegen die Emissionsbanden im NIR-Bereich, was die Detektion erschwert. Deswegen ist unklar, ob die Lebensdauer der angeregten Spezies zu kurz für die Wasserspaltung ist. Zeitaufgelöste Ultrakurzzeit-Absorptionsmessungen des angeregten Zustands könnten diese Frage klären.

## 6. Experiment Section

### 6.1. General Methods

Unless otherwise stated, all operations were carried out under an inert atmosphere of nitrogen using standard Schlenk techniques, or performed in a dry and oxygen free glove box.

THF, pentane, benzene, toluene and $\mathrm{Et}_{2} \mathrm{O}$ were distilled from sodium benzophenone ketyl under nitrogen. Acetonitrile was dried through alumina super I. $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was dried first over $\mathrm{P}_{2} \mathrm{O}_{5}$, then with $\mathrm{CaH}_{2}$. Butyronitrile was distilled from $\mathrm{CaH}_{2}$.

The following chemicals are commercially available products from the following suppliers, which were used as received unless otherwise noted:
$\mathrm{W}(\mathrm{CO})_{6}$ (Fluka); $\mathrm{Cp}^{*} \mathrm{H}$ (Merck, distilled under nitrogen and protected from light before use); $\mathrm{PCl}_{5}$ (Merck); $\mathrm{Mo}(\mathrm{CO})_{6}$ (Aldrich); 1,10-phenanthroline (Alfa Aesar); ethylene diamine (Merck); 4,4'-dimethyl-2,2'-bipyridine (Fluka); TDAE (Aldrich); PPNCl (Aldrich, recrystallized several times from $\mathrm{Et}_{2} \mathrm{O} / \mathrm{DCM}$ to remove trace of water); $\left[\mathrm{NH}_{4}\right]\left[\mathrm{PF}_{6}\right]$ (Aldrich); naphthalene (Fluka); $[\mathrm{NO}]\left[\mathrm{PF}_{6}\right]$ (Acros); $\mathrm{Ag}\left[\mathrm{PF}_{6}\right]$ (Alfa Aesar); $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]\left[\mathrm{PF}_{6}\right]$ (Aldrich).

### 6.2. Characterization Methods

## NMR-spectroscopy

| ${ }^{1} \mathrm{H}-\mathrm{NMR}$ | Bruker Avance 400, measurement frequency 400 MHz <br>  <br>  <br>  <br> Bruker Fourier 300, measurement frequency 300 MHz <br> Varian Gemini 2000 BB, measurement frequency 200 MHz <br> ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}-\mathrm{NMR}$ |
| :--- | :--- |
| ${ }^{19} \mathrm{~F}-\mathrm{NMR}$ | Bruker Avance 400, measurement frequency 100 MHz |
| ${ }^{31} \mathrm{P}-\mathrm{NMR}$ | Varian Gemini 2000 BB, measurement frequency 188 MHz |
|  | Varian Gemini 2000 BB, measurement frequency 81 MHz |

Chemical shifts are given in ppm and ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra were referenced to the resonances of residual protons of the deuterated solvent $\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}, \delta 5.32 ; \mathrm{CD}_{3} \mathrm{CN}\right.$, $\delta 1.94 ; \mathrm{C}_{6} \mathrm{D}_{6}, \delta 7.15 ; \mathrm{CD}_{3} \mathrm{OD}, \delta 3.31 ;$ THF-d $\left.{ }_{8}, \delta 3.58 ; \mathrm{CD}_{3} \mathrm{Cl}, \delta 7.26 ; \mathrm{D}_{2} \mathrm{O}, \delta 4.79\right)$.

If necessary, the assignment of the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ was confirmed by two-dimensional $\mathrm{H}, \mathrm{H}-\mathrm{COSY}$-NMR spectra. The assignment of the ${ }^{13} \mathrm{C}$-NMR signals was interpreted by two-dimensional NMR techniques (HSQC and HMBC). Unless otherwise indicated, the ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$-NMR signals are singlets.

All air sensitive samples were prepared in the glove box. For the description of the multiplets, the following abbreviations are used: s: Singlet, d: Doublet, dd: Doublet of doublet, $\mathbf{t}$ : Triplet, $\mathbf{q}$ : Quartet, sept: Septet, m: Multiplet. For paramagnetic NMR spectra, br stands for broad peak and vbr corresponds to very broad peak.

The numbering scheme used for the ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR signals is shown in Figure 6.1.

## Elemental analysis

Heraeus CHN Rapid Analyzer

## IR spectroscopy

Bruker VERTEX 70 FT-IR-Spectrometer
The samples were measured as KBr pellets or in solution. Sample preparation was carried out in a glove box. The pellet preperation and the measurements were performed in the atmosphere.

The intensities of the vibrational bands are indicated as follows: vs: very strong,
s: strong, m: medium, $\mathbf{w}$ : weak.

El mass spectrometry

VG 70S EI double focusing sector field device

## FAB mass spectrometry

VG Analytical VG/70-250-S-Spectrometer
$m$-nitrobenzyl alcohol was used as matrix. The sample sample handling was carried out in the atmosphere.

## MALDI-TOF mass spectrometry

Matrix assisted laser desorption/ionisation time-of-flight (MALDI-TOF) mass spectrometry was performed on a Bruker UltrafleXtreme mass spectrometer operated in positive ion mode with a Smartbeam II Laser. Laser power was used at the threshold level required to generate signal. For measurements in solution, DHB was used as the matrix and prepared as a solution in $30 \% \mathrm{ACN} / 0.1 \%$ TFA $/ \mathrm{H}_{2} \mathrm{O}$. Allotments of matrix and sample were thoroughly mixed together, spotted on the target plate, and allowed to dry. For measurements in the solid state, 0.1 mg of AgTFA, 0.1 mg of analyte and 20 to 80 mg of the DHB matrix (powder) was mixed in a glass vial, vortex for 2 min . Press the powder onto the MALDI target and remove all free grains or crystals.

## UV-vis spectroscopy

Varian CARY 50 Scan UV-VIS-NIR-spectrophotometer

StellarNet BLUE-Wave spectrometer

## Electrochemical methods

Electrochemical measurements were performed using a BAS 100BW potentiostat with a three-electrode configuration in a single cell. The working electrode was either a glassy carbon disk (diameter $=3.0 \mathrm{~mm}$ ) or platinum disk (diameter $=1.6$ mm ), the auxiliary electrode was a Pt wire, and the reference electrode was an Ag wire pseudo-reference, which was referenced externally vs. the $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+/ 0}$ couple. All measurements were performed at room temperature under a nitrogen atmosphere with $0.1 \mathrm{M} \mathrm{Bu}_{4} \mathrm{NPF}_{6}$ supporting electrolyte in acetonitrile or THF. The working electrode was polished between runs with an alumina slurry to achieve a mirror finish, then thoroughly rinsed with purified water and left to dry in a 40 ${ }^{\circ} \mathrm{C}$ oven. The Pt and Ag wires were polished with fine sandpaper.

For the electrochemical solvents, acetonitrile (Chromasolv ${ }^{\circledR}$, Fluka) was purified on alumina (Woelm, acidic, super I), THF (Chromasolv ${ }^{\circledR}$, Fluka) was distilled from sodium/benzophenone. All solvents were degassed before taking into a golvebox and kept in a Young solvent vessel. Water for cleaning was purified using a LaboStar ${ }^{T M}$ Range of UltraPure Water System. $\mathrm{NBu}_{4} \mathrm{PF}_{6}$ was crystallized twice from methanol, dried at $100^{\circ} \mathrm{C}$ under vacuum and used as supporting electrolyte.

## X-ray single crystal structure analysis

Bruker AXS smart APEX 3-circle single-crystal diffractometer

- APEX I CCD detector
- Molybdenum source Incoatec Microfocus Source I $\mu \mathrm{S}^{T M}$ (30 watts, air cooling)
- Cryostream nitrogen-flow cooling, 100-300 K (Oxford Cryosystems)

SuperNova 4-circle single-crystal diffractometer from Oxford Diffraction

- Molybdenum and copper source (dual unit), Microfocus tubes
- Cryostream-700 plus-nitrogen flow cooling, 100-500 K (Oxford Cryosystems)

The crystal structures were analyzed with the aid of WinGX and SHELX-97 programs, solved by direct methods and expanded using Fourier techniques. All nonhydrogen atoms were refined anisotropically and the hydrogen atoms were treated as riding model in idealized positions (HFIX 137 for $-\mathrm{CH}_{3}$ groups, HFIX

13 for tertiary CH , HFIX 23 for secondary $\mathrm{CH}_{2}$, HFIX 43 for aromatic CH$)$.

## TD-DFT calculations

TD-DFT calculations were performed with Turbomole; ${ }^{130}$ Functional:B-P86; ${ }^{131,132}$ Basis sets: def2-TZVP for W, def-SV(P) for O, N, C, H.

### 6.3. Synthetic Details

### 6.3.1. Synthesis According to Literature

The following compounds and reagents were prepared according to published procedures:

## $\mathrm{W}(\mathrm{CO})_{3}(\mathrm{NCPr})_{3}{ }^{107}$

A mixture of $\mathrm{W}(\mathrm{CO})_{6}(14.0 \mathrm{~g}, 0.040 \mathrm{~mol})$ and $\mathrm{NCPr}(140 \mathrm{ml})$ was refluxed for 4 days. The volume of the cooled reaction mixture was reduced to 25 ml , and 120 ml of diethyl ether was added to the solution. Fine yellow needles was precipitated from the solution on cooling in the fridge for 2 days. The pure product was seperated by filtration, washing with diethyl ether, and drying in vacuo.
Yield: $\geq 17.7$ g, $0.036 \mathrm{~mol}, 90 \%$.
${ }^{1} \mathrm{H}$-NMR ( $200 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}$ ), $\delta[\mathrm{ppm}]:$
$2.58 \quad\left(\mathrm{t},{ }^{3} J_{H, H}=7.0 \mathrm{~Hz}, 6 \mathrm{H}, \mathrm{NCCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\right)$
1.75 (m, $\left.6 \mathrm{H}, \mathrm{NCCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\right)$
$1.09 \quad\left(\mathrm{t},{ }^{3} J_{H, H}=7.3 \mathrm{~Hz}, 9 \mathrm{H}, \mathrm{NCCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\right)$

IR: $\nu_{C O}\left[\mathrm{~cm}^{-1}\right]=1913$ (vs), 1796 (vs) $\left[\right.$ in $\left.\mathrm{CH}_{2} \mathrm{Cl}_{2}\right]$
$\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{CO})_{3} \mathrm{H}^{108}$

A solution of $\mathrm{Cp}{ }^{*} \mathrm{H}(4.3 \mathrm{~g}, 5 \mathrm{ml}, 31 \mathrm{mmol})$ in 130 ml toluene was added to 7.6 g of $\mathrm{W}(\mathrm{CO})_{3}(\mathrm{NCPr})_{3}(16 \mathrm{mmol})$. The mixture was stirred for 2 h and then warmed
to $50-60^{\circ} \mathrm{C}$ until all solid dissolved. The resulting solution was stripped of all liquid volatiles by pumping in vacuo, then dried at $70-80^{\circ} \mathrm{C}$. The residue was purified by sublimation at $75^{\circ} \mathrm{C}$ under high vacuum.
Yield: $\geq 4.7 \mathrm{~g}, 11.7 \mathrm{mmol}, 73 \%$.
${ }^{1} \mathbf{H}-\mathrm{NMR}\left(\mathbf{2 0 0} \mathbf{~ M H z}, \mathrm{C}_{6} \mathbf{D}_{6}\right), \delta[\mathrm{ppm}]: 1.74\left(\mathrm{Cp}^{*}\right) ;-6.50$ (hydride)

IR: $\nu_{C O}\left[\mathrm{~cm}^{-1}\right]=2014(\mathrm{vs}), 1925$ (vs) [in pentane]

## $\mathrm{Cp}^{*} \mathrm{WCl}_{4}{ }^{\mathbf{1 0 9}}$

$\mathrm{PCl}_{5}(6.6 \mathrm{~g}, 31.6 \mathrm{mmol})$ was slowly added to a solution of $\mathrm{Cp}{ }^{*} \mathrm{~W}(\mathrm{CO})_{3} \mathrm{H}(5.0 \mathrm{~g}$, 12.4 mmol ) in 50 ml toluene and the mixture was stirred at $70^{\circ} \mathrm{C}$ for 17 h to give an orange solid which was filtered, washed with methylene chloride, then dried under vacuum.

## $\mathrm{Cp}^{*} \mathrm{Mo}(\mathrm{CO})_{3} \mathrm{H}^{108}$

$\mathrm{Mo}(\mathrm{CO})_{6}(6.0 \mathrm{~g}, 22.7 \mathrm{mmol})$ and 60 mL of butyronitrile were refluxed overnight in a 250 ml flask to give $\mathrm{MO}(\mathrm{CO})_{3}(\mathrm{NCPr})_{3}$. The solvent was removed in vacuo, and $\mathrm{Cp}{ }^{*} \mathrm{H}(5 \mathrm{~g}, 36.7 \mathrm{mmol})$ in 200 mL toluene was added to the residue. The mixture was stirred for 2 h and then warmed to $50-60^{\circ} \mathrm{C}$ until all solid dissolved. The resulting solution was stripped of all liquid volatiles by pumping in vacuo at 70 $80^{\circ} \mathrm{C}$. The residue, consisting primarily of $\mathrm{Cp}^{*} \mathrm{Mo}(\mathrm{CO})_{3} \mathrm{H}$, was sublimed at $55^{\circ} \mathrm{C}$ under high vacuum.

## $\mathrm{Cp}^{*} \mathrm{MoCl}_{4}{ }^{99}$

Instead of $\mathrm{Cp}^{*} \mathrm{Mo}(\mathrm{CO})_{3} \mathrm{Me}$, a solution of $\mathrm{Cp}^{*} \mathrm{Mo}(\mathrm{CO})_{3} \mathrm{H}$ dissolved in dichloromethane was added dropwisely to 2.5 equivalents of $\mathrm{PCl}_{5}$ partially dissolved in dichloromethane. After the mixture was refluxed overnight, an purple solution yielded from which microcrystalline purple $\mathrm{Cp}{ }^{*} \mathrm{MoCl}_{4}$ can be isolated.

1,10-phenantroline-5,6-dione was prepared according to a slightly modified method reported by Che. ${ }^{144}$ 1,10-phenanthroline ( $10 \mathrm{~g}, 50.5 \mathrm{mmol}$ ) was added slowly into cold concentrated sulfuric acid ( $100 \mathrm{ml}, 98 \%$ ) at $0^{\circ} \mathrm{C}$ in a three-necked, roundbottomed flask with reflux condenser. Potassium bromide ( $15 \mathrm{~g}, 0.126 \mathrm{~mol}$ ) was added below $5^{\circ} \mathrm{C}$. Fuming nitric acid ( $68 \%$, w/w, 10 ml ) was added drop wise with stirring under $30^{\circ} \mathrm{C}$. When fuming nitric acid drop over, the mixture was heated to $40^{\circ} \mathrm{C}$ for 3 h and then heated to $80-90^{\circ} \mathrm{C}$ for 1 h . Under the same temperature, the $\mathrm{Br}_{2}$ was blew by $\mathrm{N}_{2}$ and absorbed by NaOH for 4 h . The orange mixture was cooled and poured onto a mixture of ice and water, the pH was adjusted to 6-7 with aqueous saturated sodium hydroxide solution, and the solution was extracted with dichloromethane. The dichloromethane layer was dried with anhydrous magnesium sulfate, and the solvent was removed under vacuum. The residue was recrystallized from methanol to afford yellow needles of 1,10-phenanthroline-5,6-dione, $\mathrm{mp} 258^{\circ} \mathrm{C}$.
Yield: $\geq 4.9 \mathrm{~g}, 23 \mathrm{mmol}, 46 \%$.
${ }^{1} \mathrm{H}-\mathrm{NMR}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right)$, $\delta$ [ppm]: 9.09 (dd, 2H); 8.48 (dd, 2H); 7.56 (dd, 2H)

## dpq ${ }^{145}$

Ethane-1,2-diamine ( 0.5 ml ) was added to a suspension of 1,10-phenanthroline-5,6-dione ( $0.50 \mathrm{~g}, 2.38 \mathrm{mmol}$ ) in $\mathrm{MeOH}(25 \mathrm{ml})$. A red solution formed, which was stirred overnight at room temperature. The solid formed was filtered off and washed with small amounts of methanol. Recrystallization from toluene gave yellowish white crystals of dipyrido[3,2-a:2', $\left.3^{\prime}-h\right]$ quinoxoline.
Yield: $\geq 0.245 \mathrm{~g}, 1.05 \mathrm{mmol}, 44 \%$.

## ${ }^{1} \mathrm{H}$-NMR ( $400 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}$ ), $\delta[\mathrm{ppm}]:$

## bpy $(\mathrm{COOH})_{2}{ }^{146}$

4,4'-dimethyl-2,2'-bipyridine ( $5.4 \mathrm{~g}, 30 \mathrm{mmol}$ ) was dissolved in concentrated sulfuric acid ( 140 ml ). At $0^{\circ} \mathrm{C}$ potassium dichromate ( $35.2 \mathrm{~g}, 120 \mathrm{mmol}$ ) was added in small portions. Thereafter the reaction mixture was heated to $60^{\circ} \mathrm{C}$ for 2 h . The green solution was poured into ice water ( 600 ml ); the resulting precipitate was collected on a filter and washed with water until the filtrate became colorless. The pale greenish yellow solid was refluxed in nitric acid ( $70 \mathrm{ml} ; 50 \% \mathrm{aq}$.) for 4 h , poured into 300 ml ice, filtered and washed with water and acetone. The resulting white solid was dried in vacuo. Yield: 5.96 g, 24.4 mmol, 81.4 \%.

## $\operatorname{bpy}(\mathrm{COOMe})_{2}{ }^{147}$

To 4.1 g ( 16.8 mmol ) of 4,4'-dicarboxy-2,2'-bipyridine in 60 ml methanol was added 8.5 ml of concentrated sulfuric acid. After refluxing overnight, the solution was poured onto 180 ml water forming a white slurry. The pH of the slurry was adjusted to 8 with $25 \%(\mathrm{w} / \mathrm{v})$ sodium hydroxide. The product was then extracted with dichloromethane, dried over sodium sulfate and evaporated to form a white crystalline product. Melting point: $211^{\circ} \mathrm{C}$.
Yield: $\geq 3.6 \mathrm{~g}, 13.2 \mathrm{mmol}, 78.7 \%$.

### 6.3.2. Synthesis for Chapter 2

### 6.3.2.1. $\left[\mathrm{Cp}^{*} \mathrm{MoCl}_{3}\right]_{2}(1-1)$

A similar strategy by Poli ${ }^{94}$ was applied for the synthesis of complex $\left[\mathrm{Cp}^{*} \mathrm{MoCl}_{3}\right]_{2}$. $0.96 \mathrm{~g}(2.57 \mathrm{mmol})$ of $\mathrm{Cp}^{*} \mathrm{MoCl}_{4}$ was added to $12.43 \mathrm{~g} \mathrm{0.5} \mathrm{\%(w/w)} \mathrm{of} \mathrm{NaHg(62.2)}$ $\mathrm{mg} \mathrm{Na}, 2.7 \mathrm{mmol}$ ) in 40 ml toluene. The dark green solution was stirred for 6 hours at room temperature, then the solvent was removed under vacuum. The residue was extracted with 60 ml of dichloromethane, filtered and dried under vacuum. A olive green solid was obtained.
Yield: $\geq 0.69 \mathrm{~g}, 1.02 \mathrm{mmol}, 79 \%$.

## ${ }^{1} \mathrm{H}$-NMR ( $400 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}$ ), $\delta[\mathrm{ppm}]$ :

$1.99 \quad\left(\mathrm{~s}, \mathrm{C}_{5}\left(\mathrm{CH}_{3}\right)_{5}\right.$ by-product)

-4.19 (br, $\mathrm{C}_{5}\left(\mathrm{CH}_{3}\right)_{5}$ product)

### 6.3.2.2. $\left.\mathrm{PPN}^{2} \mathrm{Cp}^{*} \mathrm{WCl}_{4}\right](1-2)$

A solution of TDAE ( $38.6 \mathrm{mg}, 0.193 \mathrm{mmol}$ ) in $5 \mathrm{ml} \mathrm{CH} \mathrm{Cl}_{2}$ was added into a solution of $\mathrm{Cp}^{*} \mathrm{WCl}_{4}(159.0 \mathrm{mg}, 0.346 \mathrm{mmol}), \mathrm{PPNCl}(221.8 \mathrm{mg}, \mathrm{ca} .0 .350 \mathrm{mmol})$ in $15 \mathrm{ml} \mathrm{CH}_{2} \mathrm{Cl}_{2}$ under stirring. After 40 min , the colorless precipitate was filtered off through a glass fabric filter. The filtrate was concentrated to 20 ml and 40 ml of diethyl ether was added to the solution. The next day, brownish black crystals were separated from the solution, washed with diethyl ether and dried under vacuum.
Yield: $\geq 286 \mathrm{mg}, 0.286 \mathrm{mmol}, 83 \%$.

```

### 6.3.2.6. $\mathrm{Cp}^{*} \mathrm{~W}\left(\mathrm{COOMe}_{2} \mathrm{bpy}\right) \mathrm{Cl}_{3}(2-\mathrm{c})$

A colorless suspension of the (COOMe) ${ }_{2}$ bpy ligand ( $22.0 \mathrm{mg}, 0.081 \mathrm{mmol}$ ) in 12 ml CH 33 CN was added to a brown solution of $\mathrm{PPN}\left[\mathrm{Cp}^{*} \mathrm{WCl}_{4}\right](73.7 \mathrm{mg}, 0.074$ $\mathrm{mmol})$ in $6 \mathrm{ml} \mathrm{CH} \mathrm{Cl}_{2}$. The resulting black solution was stirred at $100{ }^{\circ} \mathrm{C}$ for 5 days to yield a dark purple solution. Single crystals suitable for X-ray diffraction were obtained from a diluted filtrate solution at room temperature.

### 6.3.2.7. $\mathrm{Cp}^{*} \mathrm{Mo}(\mathrm{dpq}) \mathrm{Cl}_{3}(3-\mathrm{a})$

A solution of the dpq ligand ( $28.7 \mathrm{mg}, 0.123 \mathrm{mmol}$ ) in $30 \mathrm{ml} \mathrm{CH}_{2} \mathrm{Cl}_{2}$ was slowly added through a dropping funnel into a solution of $\mathrm{PPN}\left[\mathrm{Cp}^{*} \mathrm{MoCl}_{4}\right](110.0 \mathrm{mg}$, 0.121 mmol ) in $10 \mathrm{ml} \mathrm{CH}_{2} \mathrm{Cl}_{2}$ under vigorous stirring. A blueish purple solid precipitated from the reaction suspension. The precipitate was washed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, then dried under vacuum.
Yield: $\geq 61.3 \mathrm{mg}, 0.108 \mathrm{mmol}, 89 \%$.

### 6.3.2.8. $\mathrm{Cp}^{*} \mathrm{Mo}\left({ }^{t} \mathrm{Bu}_{2} \mathrm{bpy}\right) \mathrm{Cl}_{3}(3-\mathrm{d})$

To a solution of $193 \mathrm{mg}(0.286 \mathrm{mmol})\left[\mathrm{Cp}^{*} \mathrm{MoCl}_{3}\right]_{2}$ in 25 ml methylenechloride, $157 \mathrm{mg}(0,586 \mathrm{mmol})$ of the ligand ${ }^{t} \mathrm{Bu}_{2}$ bpy in 7 ml of methylene chloride was added dropwisely. The resulting dark brown solution was stirred for 16 hours at room temperature and then filtered. The product $\left.\mathrm{Cp}{ }^{*} \mathrm{Mo}^{( }{ }^{4} \mathrm{Bu}_{2} \mathrm{bpy}\right) \mathrm{Cl}_{3}$ was precipitated from the filtrate by addition of diethyl ether. The black precipitate was filtered and washed several times with diethyl ether, and n-hexane to yield 263 mg ( $0.434 \mathrm{mmol}, 76 \%$ ) light brown solid.

### 6.3.3. Sythesis for Chapter 3

### 6.3.3.1. $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(4-\mathrm{a})$

400 mg of $\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq}) \mathrm{Cl}_{3}(0.608 \mathrm{mmol})$ was mixed with 20 ml degassed water to give a dark purple acidic solution. After neutralization by addition of solid NaHCO 3 , a solution of $\mathrm{NH}_{4} \mathrm{PF}_{6}(100.4 \mathrm{mg}, 0.616 \mathrm{mmol})$ in water ( 5 ml ) was added slowly and a dark purple solid precipitated from the solution. The solvent was removed under reduced pressure and the remaining solid was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The filtrate was concentrated under vacuum. The analytically pure product was precipitated through addition of diethyl ether. The solid was collected by filtration, washed with ether, dried under high vacuum. Yield: $\geq 289.0 \mathrm{mg}, 0.203$ $\mathrm{mmol}, 66.7 \%$.

### 6.3.3.5. $\left[\left(C p^{*} \mathbf{W}(d p q)(\mu-O)\right)_{2}\right](6-a)$

Complex $\left[\left(\mathrm{Cp}^{*} \mathrm{~W}(\mathrm{dpq})(\mu-\mathrm{O})\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}$ (4-a) was dissolved 3 times in acetonitrile and pumped dry, then treated with THF for 3 times in order to remove residual co-crystallized $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and acetonitrile. A solution of sodium naphthalenide prepared in situ by stirring naphthalene ( $27.3 \mathrm{mg}, 0.212 \mathrm{mmol}$ ) with an excess amount of freshly cut sodium in 3 ml THF. The green solution was filtered into a suspension of $4-\mathrm{a}(144.0 \mathrm{mg}, 0.101 \mathrm{mmol})$ in 4 ml THF under vigorous stirring. The solvent was removed from the resulting dark violet solution under reduced pressure and the residue was treated three times with pentane to remove residual

THF. The solid residue was extracted with pentane and the violet pentane solution was filtered over a glass fiber filter and dried in vacuo. The crude product was redissolved several times in pentane and dried under high vacuum to remove residual naphthalene to yield a dark violet powder. Yield: $\geq 88.0 \mathrm{mg}, 0.078$ $\mathrm{mmol}, 76.8 \%$.

## I.II. X-ray structural data

The measurement of single crystals was carried out on a Bruker APEX single crystal diffractometer with graphite monochromated $\mathrm{Mo}-\mathrm{K}_{\alpha}$-rays ( $\lambda=0.71073$ Å) at low temperatures. Suitable crystals were grown in a highly viscous polybutylene oil mounted on a glass fiber on the goniometer head. The empirical absorption correction was carried out with the program SADABS ${ }^{148}$ or numerically for indexed faces. The program SHELXS-97 ${ }^{149}$ was used for the solution of the structure (direct method). The refinement was performed with the program SHELXL-97 and the program package WinGX v1.70.01 considering all independent reflections. If not otherwise specified below, all non-hydrogen atoms were refined anisotropically. If not specified, the hydrogen atoms were refined isotropically using a riding model.

## I.II.I. $\mathrm{Cp}^{*} \mathrm{~W}($ dpphen $) \mathrm{Cl}_{3}$ (2-b)

The asymmetric unit of the structure of the complex $\left[\mathrm{Cp}{ }^{*} \mathrm{~W}(\mathrm{dpphen}) \mathrm{Cl}_{3}\right]$ contains a cocrystallized dichloromethane molecule, the non-hydrogen atoms were refined anisotropically.

| Identification code | $\begin{aligned} & \text { 2-b } \\ & \text { Cp*W(dpphen) } \mathrm{Cl}_{3} \times \text { DCM } \end{aligned}$ |

| Sodium |  | H260, H314 | $\begin{aligned} & \text { P223, P231 + } \\ & \text { P232, P280, } \\ & \text { P305 + P251 + } \\ & \text { P338, P370 + } \\ & \text { P378, P422 } \end{aligned}$ |
| Sodium hydroxide | - | H314 | $\begin{aligned} & \text { P280, P280, } \\ & \text { P305 + P351 + } \\ & \text { P338, P310 } \end{aligned}$ |
| Sodium mercury amalgam |  | $\begin{aligned} & \text { H260, H314, } \\ & \text { H330, H360, } \\ & \text { H372, H410 } \end{aligned}$ | $\begin{aligned} & \text { P201, P223, } \\ & \text { P231 + P232, } \\ & \text { P206, P370 + } \\ & \text { P378, P422 } \end{aligned}$ |
| Sulfuric acid | $\langle\hat{c}$ | H314, H412 | $\begin{aligned} & \text { P273, P280, } \\ & \text { P305 + P351 + } \\ & \text { P338, P310 } \end{aligned}$ |
| Tetrahydrofuran |  | $\begin{aligned} & \text { H225, H319, } \\ & \text { H335, H351 } \end{aligned}$ | $\begin{aligned} & \text { P210, P261, } \\ & \text { P281, P305 + } \\ & \text { P351 + P338 } \end{aligned}$ |

| Tetrakis(dimethylamino)ethylene | 垀) - है | H226, H314 | $\begin{aligned} & \text { P280, P305 + } \\ & \text { P351 + P338, } \\ & \text { P310 } \end{aligned}$ |
| :---: | :---: | :---: | :---: |
| Toluene |  | H225, H304, <br> H315, H336, <br> H361d, H373 | $\begin{aligned} & \text { P210, P261, } \\ & \text { P281, P301 + } \\ & \text { P310, P331 } \end{aligned}$ |
| Tungsten hexacarbonyl |  | $\begin{aligned} & \text { H301 + H311 } \\ & + \text { H331 } \end{aligned}$ | $\begin{aligned} & \text { P261, P280, } \\ & \text { P301 + P310, } \\ & \text { P311 } \end{aligned}$ |

## Erklärung über frühere Promotionsversuche

Hiermit erkläre ich,
Promotionsversuche unternommen worden sind, oder dass vorher keine weiteren wurden.

Hamburg, den 06.01.2014

## Eidesstattliche Versicherung

Hiermit erkläre ich an Eides Statt, dass die vorliegende Dissertationsschrift selbstständig und allein von mir unter den angegebenen Hilfsmitteln angefertigt wurde.

Hamburg, 06.01. 2014

[^0]:    * The labeling scheme is explained in Figure 2.3.

[^1]:    * $\quad \mathrm{Z} 1$ is the centroid of the Cp ring.

[^2]:    ${ }^{a}$ estimated standard deviations in parentheses
    ${ }^{b} \mathrm{Z} 1$ is the ring centroid of carbon atoms C1-C5.

[^3]:    ${ }^{a}$ estimated standard deviations in parentheses
    ${ }^{b} \mathrm{Z} 1$ is the ring centroid of carbon atoms C1-C5.

[^4]:    ${ }^{a}$ estimated standard deviations in parentheses
    ${ }^{b} \mathrm{Z} 1$ is the ring centroid of carbon atoms C1-C5.
    ${ }^{c}$ Z2 is the ring centroid of carbon atoms C35-C39.
    ${ }^{d} \alpha$ is the angle formed by planes of phen moiety in dpphen ligand.
    ${ }^{e} \beta$ is the torsion angle between two dpphen ligands.

[^5]:    * The numbering scheme of the protons used in Figure 3.4 is specified in Reaction Scheme 3.3.

[^6]:    ${ }^{a}$ estimated standard deviations in parentheses
    ${ }^{b} \mathrm{Z} 1$ is the ring centroid of carbon atoms C1-C5.

[^7]:    ${ }^{a}$ estimated standard deviations in parentheses
    ${ }^{b} \mathrm{Z} 1$ is the ring centroid of carbon atoms C1-C5.
    ${ }^{c} \mathrm{Z} 2$ is the ring centroid of carbon atoms C25-C29.
    ${ }^{d} \alpha$ is the angle between two dpq ligand planes.
    ${ }^{e} \beta$ is the torsion angle between two dpq ligands.

[^8]:    * The g-value is determined at the crossing point of the the EPR spectrum.

[^9]:    * Turbomole; ${ }^{130}$ Functional:B-P86;;131,132 Basis sets: def2-TZVP for W, def-SV(P) for O, N, C, H.

[^10]:    * The THF solution might not have been homogeneous.

[^11]:    * $\quad \mathrm{Z} 1$ and Z 2 are the centroids of the Cp rings.

[^12]:    ${ }^{a}$ estimated standard deviations in parentheses
    ${ }^{b} \mathrm{Z} 1$ is the ring centroid of carbon atoms C1-C5.
    ${ }^{c} \mathrm{Z} 2$ is the ring centroid of carbon atoms C29-C33.
    ${ }^{d} \alpha$ is the angle formed by two bipyridine planes.
    ${ }^{e} \beta$ is the torsion angle between two ${ }^{t} \mathrm{Bu}_{2}$ bpy ligands.
